[1] The Nobel Prize for medicine in 1927 was given to Dr. Julius Wagner-Jauregg "for his discovery of the therapeutic value of malaria inoculation in the treatment of dementia paralytica."

essential to the treatment, that memory loss and brain damage are severe and inescapable, that ECT "burns the brain," that its effects are like a Band-Aid to a wound, i.e., are palliative rather than relieving the cause, that so little is known of the mechanism of ECT that it should be discarded, as cupping, burning, leeching, and bleeding have been discarded.

EXAMINING THE MYTHS

The widely held beliefs discussed above are unfounded—they are the myths of electroconvulsive therapy. Neither shock nor convulsion is essential. Memory loss, which does occur, is neither permanent nor essential and can be minimized by treatment modifications so as to be a calculable risk. Brain damage, like death, is a rare event in ECT, and even its low incidence may be reduced further. Much is known about the ECT process—possibly as much or more than is known about any other treatment mode in psychiatry—and there is good evidence that cerebral seizures affect specific pathology, particularly in depressive illness.

Let us examine each ECT myth individually.

1. *"Shock and convulsion are essential":* Shock is defined as the perception of the electrical currents used to induce a seizure or as the evocation of fear, panic, and anxiety that may accompany any stressful experience. Neither type of shock is essential to the ECT process.

In the early days of ECT, seizures were unmodified by sedatives or muscle relaxants. Fear and panic often accompanied such treatments, and their prominence was believed to be essential to the treatment process (5). Today, however, treatment is given to patients who are asleep after receiving an intravenous barbiturate; the patient experiences neither panic nor pain. Seizures may also be induced by an anesthetic inhalant, flurothyl, with no electrical currents, and these treatments are as effective as ECT (6–8).

The convulsion is defined as the motor and autonomic events that accompany the cerebral events—the patterned electrical discharges that are termed the central "seizure." ECT given under complete muscle paralysis following the intravenous administration of succinylcholine is as therapeutically effective as unmodified seizures, which indicates that the motor and autonomic aspects of the convulsion contribute little to the therapeutic process. At one time, electric currents were applied without inducing a seizure. These subconvulsive currents were significantly less effective in treating depressive states and schizophrenia and were soon discarded (9–11). Trials with subconvulsive levels of metrazole and flurothyl also found that clinical efficacy was dependent on the seizure (12).

An interesting aspect of the role of seizures in ECT is seen in the "missed seizure." With threshold currents or unilateral electrode placement, incomplete seizures occasionally occur and are associated with a poor clinical response. Such incomplete seizures occur often enough for various authors to have suggested that EEG monitoring of the seizure is necessary to assure efficacy in ECT (7, 8). These observations are a further indication that electrical currents alone, without the cerebral events, are clinically ineffective.

Not only is the cerebral seizure essential, but its length is related to clinical efficacy (13, 14). When the duration of the seizure is reduced by lidocaine, ECT efficacy is also lessened (15). The present view is that the seizure is either the therapeutic event itself or a direct reflection thereof, and that neither an electric current ("shock") nor a convulsion is central to the therapeutic process.

2. *"Memory loss is permanent, and improvement depends on the degree of memory loss":* Each seizure produces changes in brain functions which persist for minutes to hours after each treatment. With successive seizures, the mental changes persist for longer periods, often for many weeks after a series of treatments. The syndrome is characterized by confusion, memory difficulty (both anterograde and retrograde), disorientation, and changes in psychological and physiological tests (16). These deficits gradually improve after the last seizure. Nevertheless, memory impairment is a frequent complaint, with 18%–67% of patients reporting defects after treatment (17–19). Examination of memory processes by objective tests, however, reveals that performance is usually at pretreatment levels or better within weeks of the last treatment. Long-term follow-up studies have failed to find persistent memory defects after six months (18, 19).

It was once thought that memory loss was central to the therapeutic process, but recent studies suggest otherwise. Depressed patients improve after few seizures, without evidence of memory loss. When electrodes are placed over the nondominant hemisphere, as in unilateral ECT, the therapeutic response is sustained, but memory loss is reduced (20, 21). The type of memory that is affected is related to the path of currents (i.e., location of electrodes), which suggests that the changes in memory functions are largely the direct effects of the current, rather than an effect of the seizure or the accompanying biochemical events (22).

Our beliefs about the role and significance of memory loss in the treatment process are complicated by the many changes in treatment methods and treatment attitudes during the past decades. In the early days of shock therapy, changes in memory were believed to be important to the therapeutic process, and memory impairment was encouraged by allowing the patient to remain apneic and cyanotic until normal breathing recurred after each seizure. Today, sedation, hyperoxygenation, unilateral electrode placement, and control of current characteristics make memory impairment and other features of the organic mental syndrome no longer a factor in the ECT process.

3. *"Shock therapy causes permanent brain dam-*

age": Brain damage is best defined by pathologic study. The data concerning sustained pathologic changes with ECT come from the examination of brain tissues of patients who died after ECT, from epileptic patients who died in status epilepticus, and from tissues of animals subjected to repeated seizures. Inferences are also made from the psychological and physiological tests that are usually interpreted as measures of an organic mental syndrome in man (16).

The definition of the pathology of ECT is complicated by the time between ECT and the time of death in published reports. Some tissues were examined after seizures that were within hours of death, but in other reports, ECT is a distant event that may or may not be related to the pathology examination. Brain tissues have been reported to show increased gliosis (23), diffuse degeneration (24), petechial hemorrhages in the brain stem with fat embolism (25), and edema and subarachnoid hemorrhage (26–28). The brain of a patient who died 15 minutes after the 12th ECT was found to be edematous and showed neuronal damage and increased lipofuscin pigmentation (29). In four autopsies of patients who died after ECT, one author reported death due to intraventricular hemorrhage in one and to cardiovascular disease in three (30). Each of these studies was done before 1956, when seizures were usually induced without succinylcholine, oxygen, or barbiturates.

The incidence of death in ECT has been reported variously from none in 8,500 treatments in 870 patients (31) to .06%, .08%, .03%, and .8% of patients treated (32–35). In most instances, death is ascribed to cardiac complications, usually after the seizure during the recovery period and rarely during the seizure itself. Higher death rates were reported for the 1940s, when treatments were usually given without drug modifications and "missed" or incomplete seizures were more common. Patients frequently experienced pain, fear, and panic—psychological events that can contribute to a cardiac death (36). In the pathology reports, missed seizures were a prelude to a number of the deaths studied. Missed seizures and subsequent panic, fear, and excitement are no longer a feature of clinical ECT. Pretreatment sedation and anesthesia are routine and probably contribute to the reduction in the number of deaths occurring with ECT.

It is difficult to negate the global judgment that ECT causes permanent brain damage. Except for persistent subjective complaints of memory defect, however, the evidence for such injury or its persistence is lacking, despite extensive study.

4. *"ECT is at best palliative; its efficacy is not equal to other therapies":* Among the beliefs with little foundation, the most pervasive is the professional myth that psychotherapy gets at the root of the patient's problems, removes the cause of the illness, and thereby prevents recurrence, while ECT and drug therapies suppress or bury the cause, so that the illness will recur. In fact, comparisons of the results of ECT with other therapies show it to be superior to drug therapies and psychotherapy in both immediate and long-term effects in depressive illness and at least equal to drug therapies, milieu therapy, and psychotherapy in schizophrenia (31, 35, 37).

The results of ECT are directly related to clinical diagnosis (31). ECT is most effective in psychotic depressive syndromes and mania; success rates are 60%–90% of cases selected. Patients with diagnoses of bipolar depression, unipolar depression, involutional depression, and depression of old age are rapidly responsive, usually requiring 2–4 seizures spaced at 48-hour intervals to elicit an elevation of mood, relief of suicidal preoccupation and agitation, and reversal of the symptoms of hypothalamic dysfunction. In most instances, the "course" is completed with 6 to 8 seizures, a number that seems constant regardless of whether seizures are induced electrically using bilateral or unilateral electrode placements (20, 21) or by flurothyl (8). Maintenance seizures are rarely needed, although subsequent treatment with antidepressant drugs sustains improvement better than the use of sedative drugs (38) or no maintenance drugs (39, 40). ECT is effective compared with placebo (41–43), psychotherapy (44), simulated ECT or subconvulsive treatments (10, 11, 45), and antidepressant drugs (41, 46–54).

The data regarding suicide are impressive. A shorter hospital stay and a lower suicide rate for ECT-treated patients compared with those treated by psychotherapy alone were reported in one early study (44). Another study reported 9 deaths in 109 patients treated by psychotherapy alone compared with 1 death in 88 patients treated with ECT (55).

In a 3-year follow-up study of 519 depressed patients treated by ECT, antidepressants, or neither in the decade 1959–1969, Avery and Winokur (56) reported a lower fatality rate for the ECT-treated patients than the other two groups.

The efficacy of ECT also is seen in the comparisons of different methods of inducing the seizure. Studies comparing ECT with unilateral and bilateral electrode placements find the two methods have essentially similar efficacy (20, 21), as do comparisons of seizures induced electrically with those induced by an inhalant, flurothyl (8). The efficacy of repeated seizures is related more to the clinical diagnosis than to the type of seizure induction.

The usefulness of ECT in the treatment of schizophrenia is cited in standard psychiatric texts (35, 37). Controlled studies, however, find little difference between ECT and psychotropic drugs, milieu therapy, or insulin coma therapy in type of outcome, duration of hospitalization or illness, or in incidence of recurrence (31, 57).

In 9 of 10 open clinical studies of acute schizophrenics, an average of 75% improvement in clinical ratings and in discharge rate has been reported, with one study reporting a 30% rate (31). Few studies are controlled. Twelve studies used a historical control, comparing treatment results with those of treatments be-

fore ECT was introduced. In 10 of these reports, ECT was found to be superior, with a 50%–70% improvement rate contrasted with a 30% rate for the earlier period, but 2 reports found no advantage for ECT (31,56). Other studies compared ECT and psychotropic drugs and found similar discharge rates (31, 56, 58).

In chronic schizophrenia, clinical efficacy is less well defined. In 4 controlled clinical trials, no differences were reported between ECT and 1) anesthesia alone, 2) ECT with anesthesia, or 3) subconvulsive currents (59); between ECT and simulated ECT (60); between ECT alone and ECT with succinylcholine (Anectine), ECT with sodium thiopentol (Pentothal), sodium thiopental alone, or nitrous oxide (61); or between ECT and milieu therapy, psychotherapy alone, or psychotherapy combined with psychotropic drugs (62). In a follow-up of the last mentioned study, May and Tuma indicated that the long-term results with ECT were equal to, and often better than, the other therapies (63). These evaluations of ECT in chronic schizophrenia are seriously flawed, however, by inadequate dosage. Despite the clinical experience that schizophrenic patients require an average of 20 seizures for clinical efficacy, each of these controlled studies used fewer than 20 treatments. In some early reports (64) and in more recent assessments, intensive ECT has been reported to elicit better clinical effects than drug therapy alone as measured in work record, number and duration of rehospitalizations, and need for further treatment, suggesting that dosage may be a critical factor in the results of chronic schizophrenia (65).

Part of the confusion in evaluating efficacy results from the paucity of well-designed studies and the complexity of the outcome criteria. The principal evaluations of ECT were done between 1940 and 1960, when mental hospitals were in the transition from closed asylums to open community hospitals and the science of control studies and independent evaluations was yet to be developed.

Every new therapy is broadly applied initially; later its role is refined to a limited number of mental conditions. For ECT, the claim that its use in depression is purely palliative and less effective than other therapies is contrary to the published data. For other psychiatric states, where its efficacy is poorly defined, ECT may or may not be as effective as other therapies, and there is a need for further assessments of its efficacy and safety.

5. *"The mode of action of ECT is unknown; hence, it should not be used":* There are two aspects to this belief—that ECT's mode of action is unknown, and that this is a reasonable basis for it to be discarded.

If a lack of understanding of the mode of action were a sufficient basis for the withdrawal of a medical therapy, we would have to discard not only ECT but all therapies used in psychiatry, including psychotherapy, the drug therapies, and behavior therapy.

But our knowledge of ECT is not so meager, and we know much about its mode of action (66). It is well defined that the seizure—the cerebral and biochemical events that accompany and follow the fit—is essential to a therapeutic result, whereas the convulsion itself or the mode of induction of the seizure contributes little to the treatment's efficacy.

Oxygenation, sedation, and muscle paralyzing agents reduce the complications of ECT without significantly altering its efficacy. Consideration of current strength, frequency of seizures, and electrode location reduce side effects without significantly affecting efficacy. Changes in memory, the organic psychotic reaction, and fear bear no direct relation to the treatment process.

We also know that the best predictor of the response to ECT is individual psychopathology. The efficacy of ECT is most clearly defined in depressive psychoses. Depressed patients require the fewest seizures (an average of 4–7) to achieve a reduction in both their psychosis and in the symptoms of hypothalamic dysfunction that frequently accompany depression. In acute and chronic schizophrenia and in mania, more seizures (an average of 15–30), often with greater frequency, are necessary to obtain clinical benefit. The response to ECT in such patients is often associated with an organic mental syndrome.

Changes in language, memory, EEG, and performance on a wide range of psychological tests accompany each seizure and persist for longer periods with each additional treatment. These changes gradually revert to pretreatment levels within weeks of the last seizure. While the measured changes are features of the seizure process, they are associated with, but not causally related to, the treatment outcome.

Extensive biochemical events accompany and follow the seizure. Almost any index in blood, CSF, tissues, or urine that can change with stress changes with each seizure. How is one to define the *significant* biochemical events? One suggestion is to focus on those changes which have a time course and intensity that parallel the behavioral events (67).

Such events may include persistent increase in catecholamines, reflected best in the increase in brain and CSF monoamine oxidase (68). Cholinesterase levels increase, suggesting that acetylcholine may be a factor in ECT (69, 70). Protein synthesis is inhibited, and blood constituents show the changes of the stress response, which are probably nonspecific with regard to the ECT process (71, 72). Hypothalamic functions, which were abnormal during the illness, show a return to normal levels: sleep, appetite, and libido improve; weight increases; and menstruation returns. Few chemical measures of hypothalamic function have been taken, but the diurnal curve of cortisol excretion was found to be flat during depression and to be more like a normal diurnal curve after an ECT-induced recovery (73).

There is a similarity between the status of ECT today and that of psychotropic drugs in 1957–1962, a period when scientists were finding that the distinctions among the antipsychotic drugs could be re-

lated not to the chemical structures of the compounds but to clinical diagnosis and physiological response. The diverse actions of thymoleptics, stimulants, MAO inhibitors, lithium, and antipsychotic drugs in the treatment of depressions and psychoses do not allow a unitary theory of their mode of action; a pluralistic view is required. The ECT process, while superficially similar in different cases, should also be viewed as being different for different psychopathologies. In schizophrenia, in contrast to depression, the prevailing data do not allow a biochemical formulation but only a psychologic one, in which organic mental changes play a central role that is as yet poorly defined.

SUMMARY AND CONCLUSIONS

At this juncture we can review the argument. From a group of heroic therapies developed in the 1930s, many have been discarded and one, ECT, remains clinically useful. It has undergone many modifications, so much so that the treatment today is significantly different from that first introduced more than 40 years ago. However, misconceptions about the process, its efficacy and safety, and its mode of action, persist (74). The myths and attitudes have contributed to the legal restrictions in the use of ECT, to its infrequent use in public institutions, and to a decreased interest among researchers. Perhaps the psychiatric profession should be grateful to the California legislature and that state's young activists, and to the criticism of Friedberg (4), Pribram (3), and Viscott (2), who have alerted our profession to the need for a reassessment of ECT.

We cannot ignore allegations of abuse of ECT, for we are committed to a policy of self-discipline that can operate only if each allegation is investigated and corrected. Medicine has failed to use its inherent powers of self-discipline to police its practitioners and its institutions, and the present malpractice crisis is the result. The recent effort by the Massachusetts Department of Mental Health to set ECT guidelines and its annual review of the use of ECT is one approach (75, 76). Standards for ECT practice must be set by the profession, and each allegation should be investigated promptly. Where abuse is found, reeducation or censorship should be implemented.

Relinquishing our myths and changing our clinical attitudes toward ECT can only improve the present unrest and common allegations of abuse. By so doing, we can reduce the call for legal proscriptions and encourage more controlled clinical and basic research into this interesting and useful method of psychiatric therapy.

ECT and Memory Loss

BY LARRY R. SQUIRE, PH.D.

The author reviews several studies that clarify the nature of the memory loss associated with ECT. Bilateral ECT produced greater anterograde memory loss than right unilateral ECT and more extensive retrograde amnesia than unilateral ECT. Reactivating memories just before ECT did not produce amnesia. Capacity for new learning recovered substantially by several months after ECT, but memory complaints were common in individuals who had received bilateral ECT. Other things being equal, right unilateral ECT seems preferable to bilateral ECT because the risks to memory associated with unilateral ECT are smaller.

MEMORY LOSS has long been recognized as a prominent side effect of ECT. For a decade or two after the introduction of ECT, loss of memory was often believed to contribute to ECT's therapeutic effect (1). Today the view is considerably different. Several investigators have demonstrated that the extent of memory impairment is not correlated with clinical improvement (2–4). In addition, although right unilateral ECT (5) results in markedly less memory impairment than conventional bilateral ECT (6–9), it is clinically as effective, or nearly as effective, as bilateral ECT (10). Thus the available evidence supports the contention that memory loss is an undesirable side effect of ECT that is not related to therapeutic efficacy.

Like the organic amnesias that result from head trauma (11), Korsakoff psychosis (12), diencephalic tumor (13), and temporal lobe dysfunction (14), the amnesia associated with ECT is both anterograde and retrograde. Several general reviews of ECT's amnesic effects are available (15–17). In this paper I will describe recent studies that further clarify the nature and extent of memory impairment.

The first study compared the anterograde amnesic effects of bilateral ECT with the effects of right unilateral ECT. The second described retrograde effects of ECT on remote memory. The third reported findings involving the reinstatement procedure. (Results with this procedure in animal studies suggest that learned material not ordinarily affected by electroconvulsive shock may be forgotten if a reminder of the material is presented just before the shock is administered (18–20). These reports raise the possibility that eliciting depressive ideation just before administering ECT could be therapeutically advantageous because ECT might produce amnesia for such ideation.) The final study considered memory capacity in terms of objective and subjective estimates of ability many months after ECT.

ANTEROGRADE AMNESIA FOLLOWING BILATERAL OR RIGHT UNILATERAL ECT

It has been demonstrated repeatedly that bilateral ECT produces a greater impairment of new learning capacity than right unilateral ECT (6–9). In virtually all of these studies, however, learning ability has been assessed with verbal memory tests that are particularly sensitive to dysfunction of the left cerebral hemisphere. It is therefore possible that if memory were assessed with nonverbal tests designed to detect dysfunction of the right hemisphere the amnesic effect of right unilateral ECT might be similar to or greater than the amnesic effect of bilateral ECT. In two studies of patients receiving bilateral or unilateral ECT (6, 21), impairment of nonverbal memory associated with bilateral ECT was found to be slightly greater than the impairment associated with right unilateral ECT. However, in the absence of information about how patients with identified unilateral cerebral lesions perform on these nonverbal memory tests, it is difficult to be sure how specifically sensitive they were to right unilateral dysfunction.

My associates and I have recently assessed verbal and nonverbal memory before and after ECT in patients receiving bilateral or right unilateral treatment. To assess verbal memory, patients were read a short story and then immediately asked to recall as much of it as possible. Delayed recall was tested again 16–19 hours later. Patients with identified dysfunction of the left temporal lobe are known to perform more poorly on this test than patients with similar dysfunction of the frontal, parietal, or right temporal regions (22). To assess nonverbal memory, patients

FIGURE 1
Delayed Retention Scores on Verbal and Nonverbal Memory Tests for Patients Receiving Bilateral ECT (N=15) or Right Unilateral ECT (N=9).

were asked to copy a complex geometric design (23, 24). Without forewarning the same patients were asked to copy the design from memory 16–19 hours later. Patients with right temporal lesions are known to be deficient on this memory task, but patients with left temporal lesions exhibit no impairment (25). Tests were administered 1–2 days before ECT and again with equivalent forms 6–10 hours after the fifth treatment of the series.

Figure 1 shows that before ECT patients in the bilateral group and the unilateral group were nearly identical in delayed recall of the story and in delayed reproduction of the geometric figure. After ECT, patients in the bilateral group showed greater impairment in both verbal and nonverbal memory than patients in the unilateral group. Delayed recall of the story was significantly impaired in the bilateral group ($p<.01$) but not in the unilateral group ($p>.3$). (Differences between and within groups were assessed with t tests.) The scores of the bilateral and unilateral groups were significantly different ($p<.01$). Delayed reproduction of the geometric figure was significantly impaired by bilateral ECT ($p<.01$), and the difference between the scores of bilateral and unilateral groups was just short of significance ($p<.09$).

It has sometimes been assumed that right unilateral ECT causes as much memory impairment as bilateral ECT in aspects of memory function identified with the right hemisphere. Our present results clearly indicate that bilateral ECT impairs memory to a greater extent than right unilateral ECT, regardless of whether the tests used to assess memory are more sensitive to left or right hemispheric dysfunction.

This finding may mean that after unilateral ECT the unaffected hemisphere can always contribute to some extent to performance. This idea is supported by the observation that bilateral medial temporal surgery affects both verbal and nonverbal memory to a greater extent than unilateral temporal surgery (25).

RETROGRADE AMNESIA FOR REMOTE EVENTS

It has been reported that convulsive therapy can cause retrograde amnesia for events that occurred close to the time of treatment (15–17). It is now clear that retrograde amnesia can also extend to events that occurred many years before treatment (8, 26, 27). My associates and I have recently assessed remote memory with objective tests that ask about relatively familiar past events. In one test patients were asked to recognize the names of television programs that were broadcast for a single season from 1957 to 1972 (28). The programs, selected from different time periods, were exposed to national audiences to about the same extent, and memory for these programs was acquired close to the time the programs were on the air. Patients who had had a course of bilateral ECT took one form of this test before ECT and another form 1 hour after the fifth ECT.

ECT caused a temporal gradient of impairment in long-term memory (8, 29). Programs broadcast 1–3 years before ECT were forgotten; programs broadcast 4–17 years before ECT were remembered as well after ECT as they were before. Further work indicated that right unilateral ECT caused no deficit in remote memory as measured by this test. Finally, the memory loss associated with bilateral ECT was largely recovered 1–2 weeks after the completion of treatment.

We have also confirmed the clinical impression that in amnesic patients memory for temporal order is more impaired than other aspects of memory (27). Patients were shown sets of three names of television programs and were asked to choose which program was broadcast most recently. In each set of three the correct program name had been broadcast for one season from 1962 to 1973 and the two incorrect program names had been broadcast from 1957 to 1968. After five bilateral treatments, patients developed a marked impairment in their ability to make temporal judgments about this material. The impairment was temporally graded, extending to events that occurred 4–7 years before treatment but not to events that occurred 8–16 years before treatment. The deficit for temporal order information was more persistent than the deficit for recognition of program names and remained unchanged 1–2 weeks after the completion of treatment. Further work is needed to determine how long this deficit remains.

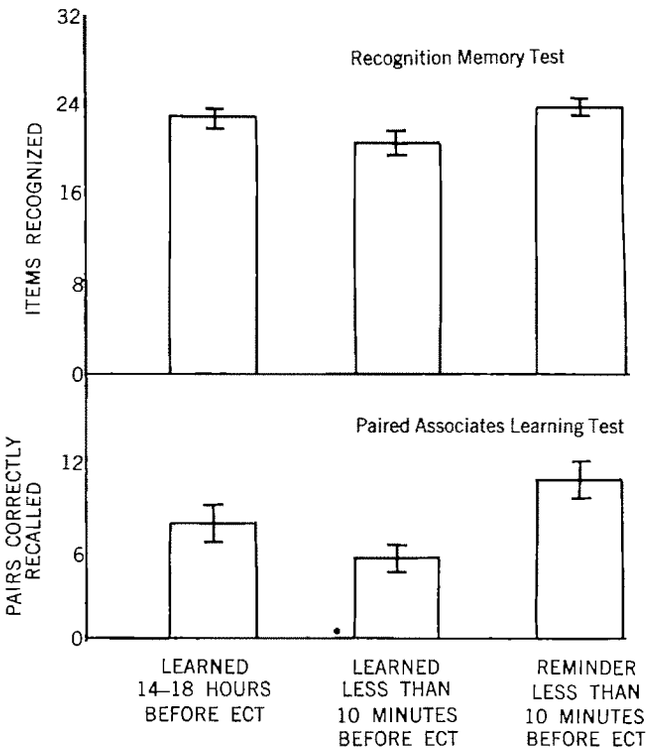
These results indicate clearly that the amnesia associated with bilateral ECT affects not only recent events but also events that occurred many years before treatment. They also indicate that bilateral ECT produces greater retrograde amnesia than right unilateral ECT. Right unilateral ECT caused no measurable loss of memory for remote events; in contrast, a stan-

dard course of bilateral ECT led to an impairment in memory for remote events that persisted for at least 2 weeks.

REINSTATEMENT

Normally, the severity of retrograde amnesia is inversely related to the time interval between learning and amnesic treatment. However, several animal studies have suggested that material not ordinarily affected by convulsive stimulation may be forgotten if a reminder is presented just before treatment (18–20).

To assess the reinstatement phenomenon with human subjects my associates and I conducted a study in which inpatients receiving bilateral ECT learned material 18 hours before ECT or about 10 minutes before ECT (30). Alternatively, patients learned material 18 hours before ECT and then were given a reminder a few minutes before ECT. Retention was tested 6–10 hours after ECT. The upper portion of figure 2 shows the results for a 32-item recognition task; the lower portion of the figure shows the results for 18 paired associates. Patients who learned material 18 hours before ECT consistently showed better retention than patients who learned material only a few minutes before ECT ($p<.05$ by t test). Patients given a reminder just before ECT of material learned 18 hours before retained this material as well as or better than patients not given a reminder. Thus, recalling material from memory just before ECT did not produce amnesia. If anything, the reminder procedure improved retention.



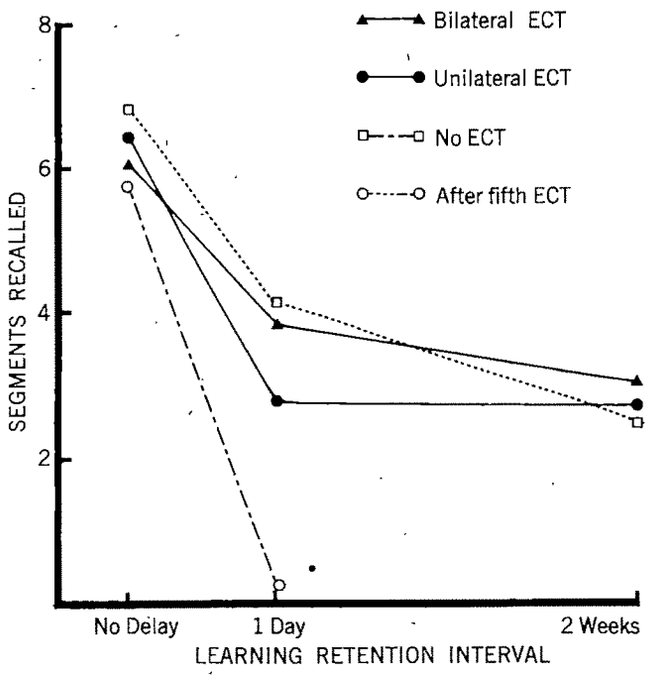
These results cannot rule out the possibility that amnesia might have occurred if the interval between the reminder and ECT had been shorter than the 3 minutes required for administration of medication. Nevertheless, it is clear that amnesia need not occur even when a reminder is given at a time before ECT when memory for newly learned material is disrupted. This finding is of clinical interest because of the possibility that the reminder procedure might be used advantageously with depressed psychiatric patients to improve the effectiveness of ECT. The results of this study provide no evidence that such a procedure would be effective in a clinical population.

LONG-TERM EFFECTS OF ECT ON MEMORY

My associates and I have conducted a long-term follow-up study of patients who had received bilateral ECT, right unilateral ECT, or hospitalization without ECT 6–9 months previously (31). Memory functions were assessed with five different tests of new learning and a test of remote memory capacity; self-ratings of memory functions were also obtained from all subjects. A group of inpatients who at the time of testing were receiving a course of bilateral ECT was also included.

The three follow-up groups did not differ from each

FIGURE 2
Retention Scores for 12 Patients on a Recognition Memory Test and a Paired Associates Learning Test



other on any of the memory tests. However, the group tested a few hours after the fifth bilateral ECT was impaired on all of the memory tests. Figure 3 shows the results for one of the memory tests. As might be expected, the inpatients had more memory impairment than the other groups. There was no significant difference between the retention scores of the three follow-up groups ($p>.3$ by analysis of variance).

Although no objective evidence was obtained in this study for persisting memory impairment long after ECT, we found in this relatively small sample ($N=31$) that subjects who had received bilateral ECT reported frequently that their memory was not as good as it used to be (31). Further study of memory complaints involving a larger sample of subjects who had received bilateral ECT or right unilateral ECT 6–9 months before ($N=70$) indicated that of the 55 subjects who had received bilateral ECT (mean number of treatments=9.9), 37 (67%) indicated that their memory was not as good as it used to be. By contrast, of 15 subjects who had received right unilateral ECT (mean number of treatments=9.4), 4 (27%) felt that their memory was impaired. (Individuals with memory complaints related only to the period of hospitalization were not scored as having perceived memory impairment.)

Such asymmetry in the distribution of memory complaints of bilateral and right unilateral groups could have occurred by chance less than 1 in 50 times (by chi square test). Most of the subjects with complaints felt that ECT was the cause of their memory problems.

FIGURE 3
Memory Test Scores for Patients Tested 6–9 Months After Bilateral ECT (N=16), Right Unilateral ECT (N=10), and No ECT (N=12) and for Inpatients Tested 6–10 Hours After Their Fifth Bilateral ECT (N=15)

Eleven of the 37 subjects who had complaints after bilateral ECT selected from four statements the one they felt best described their circumstances. None felt that they had "severe memory problems that interfere with almost everything I do"; 2 felt that they had "many memory problems that are disturbing and that occur frequently"; 6 felt that they had "minor memory problems that occur frequently"; and 3 indicated that they had "only an occasional minor problem."

Unfortunately, the discrepancy between subjective and objective measures of memory function cannot be conclusively resolved at this time. For example, the possibility cannot be ruled out that failures of recall persist after ECT that are not detected by conventional memory tests. We also cannot rule out the possibility that patients receiving bilateral ECT were different from patients receiving unilateral ECT in some way that favored the development of memory complaints. For example, patients receiving bilateral ECT might have initially been more depressed than patients receiving unilateral ECT, or they might initially have had different expectations about memory impairment. Thus it should not be concluded that bilateral ECT causes persistent memory complaints in any depressed patient. However, it seems quite clear that individuals judged clinically appropriate for bilateral ECT do have memory complaints long after ECT.

One possibility that must be considered is that bilateral ECT itself might lead to a lingering sense of memory impairment. Thus the marked impairment of recent and remote memory initially associated with bilateral ECT might cause some individuals to be more sensitive to subsequent failures in recall, even if they occur at a normal frequency. According to this hypothesis, unilateral ECT, which causes less memory impairment than bilateral ECT, would not be expected to lead to memory complaints. In its strongest form, this explanation of memory complaints supposes that bilateral ECT might lead many individuals (with or without psychiatric illness) to have a persistent illusion of memory impairment. It is too early to accept or reject any of the hypotheses outlined here; further work is needed before it will be possible to choose among them.

CONCLUSIONS

The findings reviewed above lead to the following general conclusions about ECT and memory loss: 1) bilateral ECT is associated with greater anterograde amnesia than right unilateral ECT, even when memory is assessed with tests known to be particularly sensitive to dysfunction of the right cerebral hemisphere; 2) bilateral ECT also produces more extensive retrograde amnesia for remote events than right unilateral ECT; 3) the activation just before ECT of previously learned material does not cause amnesia for that material; 4) memory substantially recovers 6–9 months after the completion of bilateral or right unilateral ECT, but persisting memory complaints are common in individuals who receive bilateral treatment.

Many different opinions have been expressed about ECT and about the memory loss that accompanies it. In view of the facts presented here, together with the considerable body of information available about ECT, opinions and clinical impressions no longer seem sufficient in most discussions about memory loss and ECT. The experimental findings reported here summarize what is now known about the risks of ECT to memory functions. All other things being equal, right unilateral ECT is preferable to bilateral ECT because the risks to memory associated with unilateral treatment are smaller than the risks associated with bilateral treatment. These risks should be considered together with the benefits of ECT to provide a basis for clinical judgment.

Efficacy of ECT in Affective and Schizophrenic Illness

BY MILTON GREENBLATT, M.D.

The author reports on studies of the comparative efficacy of ECT, the newer psychotropic drugs, and combinations of both in the treatment of depression and schizophrenia. He concludes that ECT is indicated for acutely suicidal and other severely impaired depressive patients but not necessarily for schizophrenic patients, although ECT has been successful with some schizophrenic patients for whom drugs were ineffective.

THE THERAPEUTIC VALUE of convulsive therapy has been recognized for 40 years. My personal recollections go back to 1939, shortly after the introduction of pentylenetetrazol (Metrazol), when as a medical student I was allowed to inject the drug into chronically ill patients at Worcester State Hospital in Massachusetts against their terrified and frightened resistance, which, I might add, was overpowered by several burly attendants. In those days we required only the approval of the patient's next of kin for this procedure; we had few qualms about proceeding against the patient's physical

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Greenblatt is Professor of Psychiatry, University of California, Los Angeles, School of Medicine, Los Angeles, Calif., and Chief of Staff, Veterans Administration Brentwood Hospital, Wilshire and Sawtelle Blvds., Los Angeles, Calif. 90073.

resistance. Those who now regard ECT as barbaric will be interested to learn that when ECT replaced pentylenetetrazol, it was hailed as a great humanistic triumph because the patient no longer suffered the awful preseizure sensations that accompanied the pentylenetetrazol injection; furthermore, patients given ECT were fortunate to have a period of amnesia after the treatment.

Such gratifying modifications in technique as the reduction, rectification, and commutation of current soon followed the introduction of ECT. These modifications made it possible to induce a seizure by the least jolt, so to speak. Preconvulsive barbiturate anesthesia, suppression of motor response by succinylcholine chloride (Anectine), and positive pressure oxygenation to ease the return to respiratory equilibrium were also introduced. More recently, unilateral nondominant ECT has been touted as greatly mitigating the organic features of the post-shock period (1, 2), allowing more treatments to be given in a shorter period of time.

We always regarded it as unfortunate that the terms "shock treatment" and "convulsive treatment" have hung on because they are still frightening to patients and their families. Even the term "electrotherapy" conjures up bad images in anxious patients. Nevertheless, ECT has dominated the treatment scene for many years; indeed, for a long time it was the only dramatically effective therapy in the psychiatric armamentarium. Thousands of patients thought to be doomed to long months of suffering from depression, involutional psychosis, or schizo-affective disorders were granted a new lease on life through ECT. The treatment not only helped patients but also was an unquestioned boon to psychiatry as a profession; psychiatry suddenly began to earn a little respect in medical circles and from the general public.

The efficacy of ECT has been the subject of two reports of the Group for the Advancement of Psychiatry, one in 1947 (3) and one in 1950 (4). These reports stated that although no adequate theory explained the mode of action of ECT, the treatment materially shortened the duration of psychotic depression, involutional depression, and depression associated with organic brain disease and was beneficial for some patients with neurotic depression. ECT was recognized as effective in the manic phase of manic-depressive illness, in schizophrenia with affective disorder, and in organic psychosis with excitement (e.g., catatonia), but it was contraindicated for patients with psychosomatic disease, psychopathic personality, behavior disorders of childhood, and neuroses other than neurotic depression. The Frankel Task Force reaffirmed this in 1973 (5).

Studies in the literature suggest that best results from ECT occur in patients with a family history of depression who manifest psychomotor retardation, early morning awakening, weight loss, and guilt. In other words, the treatment is effective for patients with classical clinical features of endogenous depression (1, 6, 7). When ECT is used in schizophrenic patients, more favorable results occur if the illness is of short duration, features major affective elements, has an identified precipitating event, and involves a well-adjusted premorbid personality (5).

TABLE 1
Minimum and Maximum Dosages of Various Drugs and Number of ECT Treatments Used In 8 Weeks

Item	Minimum Dose or Number of Treatments	Maximum Dose or Number of Treatments
Isocarboxazid	40 mg	60 mg
Imipramine	200 mg	250 mg
Phenelzine	15 mg	60 mg
Amitriptyline	50 mg	150 mg
ECT	9 treatments (3 per week)	Left to discretion of project physician

COMPARATIVE EFFECTIVENESS OF ECT AND DRUGS IN DEPRESSION

With the advent of the newer psychotropic drugs came the question of the comparative effectiveness of ECT versus the tricyclics and monoamine oxidase inhibitors. This has been dealt with extensively in two major studies, one by my associates and me at the laboratory of the Massachusetts Mental Health Center in 1959–1966 (8–10) and one from a collaborative study in England in 1965 (11). Taken together, these studies investigated the comparative efficacy of somatic therapies for more than 600 hospitalized depressed patients and obtained essentially the same findings.

The American Study

Our study involved 352 depressed patients admitted to three state hospitals in the Commonwealth of Massachusetts. The patients had the following diagnoses: 27.0% had manic-depressive depression (N=95); 19.3% had involutional depression (N=68); 8.2% had psychotic depressive reaction (N=29); 18.2% had psychoneurotic depressive reaction (N=64); 7.7% had depression with other psychopathology (N=27); and 19.6% had schizo-affective depression (N=69). These patients were randomly treated with either ECT, imipramine (Tofranil), amitriptyline (Elavil), phenelzine (Nardil), isocarboxazid (Marplan), or placebo. Imipramine and amitriptyline are tricyclic compounds; phenelzine and isocarboxazid are monoamine oxidase inhibitors.

The dosages used over an 8-week treatment period are shown in table 1. The schedule of observational evaluations of patients is shown in table 2. After the 8-week treatment period our results showed considerable differences in improvement in patients given the various treatments. Table 3 shows the percent of patients who showed marked or moderate improvement in each group, and table 4 shows the results of

TABLE 2
Schedule of Observational Evaluations of Patients

Measure	Time of Observation	Staff Member Who Collected Data
Depression Rating Scale (12)	Before treatment and weekly	Hospital physician and team physicians
Ward observation inventory	Before treatment and weekly	Ward nurses
Mental status symptom checklist	Before treatment and at discharge	Hospital physician and team physicians
Family and social background inventory	Completed by third week of hospital stay	Project social worker
Clinical side effects protocol	Before treatment and weekly	Hospital physician
Assessment of recovery	At discharge	Hospital physician
Follow-up interview	Annually	Project social worker

TABLE 3
Patients Who Improved Markedly or Moderately with Various Treatments (N=352), in Percents

Treatment	Patients Who Improved
ECT	92.9
Phenelzine	75.0
Imipramine	74.4
Amitriptyline	71.9
Placebo	64.2
Isocarboxazid	55.8

TABLE 4
Statistical Analyses of Differences Between Patients with Marked Improvement and Those with Moderate or No Improvement

Comparison	Chi square	Significance
ECT versus isocarboxazid	35.55	$p<.001$
ECT versus placebo	20.87	$p<.001$
ECT versus imipramine	13.00	$p<.001$
ECT versus amitriptyline	10.60	$p<.01$
ECT versus phenelzine	9.15	$p<.01$
Imipramine versus isocarboxazid	7.38	$p<.01$
Phenelzine versus isocarboxazid	6.97	$p<.01$

statistical analyses of the differences between patients who showed marked improvement and those who showed only moderate improvement or no improvement at all. These analyses clearly reveal that ECT was significantly superior to isocarboxazid, placebo, imipramine, amitriptyline, and phenelzine.

In following the status of patients over time we noted that ECT produced the fastest amelioration of symptoms; imipramine was next. The other treatments—isocarboxazid, phenelzine, and placebo—seemed to show less satisfactory results on a time scale. The greater efficacy of ECT was clearly obvious at 3 weeks (10, p. 585).

Other findings of our study as well as their implications for somatic therapy include the following:

1. ECT is indicated for acutely suicidal patients; improvement can be expected after 3–6 treatments.
2. Imipramine or phenelzine is indicated for patients who are not acutely suicidal; if no improvement occurs after 3 weeks, ECT is indicated.
3. Imipramine or a monoamine oxidase inhibitor may be effective for minimally impaired patients.
4. All of the medications, placebo, and ECT produced side effects.
5. If the patient shows no response to medication in 2–3 weeks, increasing the dose is usually unavailing.
6. Antidepressant medication may increase nondepressed schizoid symptoms in schizo-affective patients.
7. The fact that some patients responded positively to placebo points to the value of a supportive milieu.
8. ECT produced the most marked improvement in severely impaired patients. Next in effectiveness were imipramine and amitriptyline. Phenelzine and isocarboxazid were the least effective.

The British Study

The results of a short-term (4-week) British study of 250 depressed patients comparing ECT with imipramine, phenelzine, and placebo (11) were quite similar to our findings in the United States. They confirm that for the most severely ill depressed patients ECT was outstanding, that improvement occurred faster with ECT than with any other treatment, and that ECT doubled the rate of improvement over placebo, especially in women. However, as in our study, the results with placebo alone were substantial.

To assess long-term results the same researchers followed discharged patients for up to 6 months, taking note of crossover or supplementary treatment prescribed by the clinicians who followed the patients. The authors' summary noted that ECT and imipramine were the most satisfactory treatments overall. About one-third or less of the patients were satisfactorily improved with either placebo or phenelzine, and about one-half were satisfactorily improved with either ECT or imipramine. ECT was used as a supplementary treatment more often than any other, and it was used more often with phenelzine or placebo than with imipramine. As indicated above, women responded better to ECT, and men appeared to respond better to imipramine. Women who were initially given drugs eventually required more ECT than did men.

COMPARATIVE EFFECTIVENESS OF ECT AND DRUGS IN SCHIZOPHRENIA

May's impressive 1968 study comparing ECT with ataractic drugs alone, drugs plus psychotherapy, psychotherapy alone, and milieu therapy alone in 228 schizophrenic patients (13) showed that drugs plus psychotherapy and drugs alone provided the best results. Psychotherapy and milieu treatment provided the least improvement, and ECT showed improvement in approximately the middle of the range. The schizophrenic patients in this study were considered as having "middle" prognoses, i.e., they were neither on the way to spontaneous recovery nor likely to require more than 2 years of continuous hospital care under the conditions at Camarillo State Hospital in California.

Gilligan's exhaustive 1965 review of the treatment of schizophrenia (14) showed that there was substantial agreement at that time that chlorpromazine was more effective in the treatment of chronic schizophrenia than ECT.

In his 1975 review of ECT treatment of schizophrenia (15) May tried to make sense of the many conflicting reports on the subject. A fair conclusion would seem to be that drugs are generally superior to ECT in the treatment of schizophrenia, but ECT has been successful in some cases in which drugs have failed. On the other hand, May pointed out, a number of studies have claimed that ECT is no better than placebo. Studies of the relative efficacy of ECT and psychotherapy, insulin, or psychosurgery are inadequate or lacking; there are no controlled studies of the comparative usefulness of ECT in schizo-affective disorders.

COMBINATIONS OF ECT AND DRUGS

Systematic consideration of combinations of ECT with drugs in the treatment of depression and schizophrenia has been the subject of some recent reports. The question is, can something be gained through such combinations that would benefit patients more than using ECT alone? We are indebted to Abrams for his thorough review of this problem as of 1975 (16).

Depression

Abrams cited six studies involving a total of more than 500 depressed patients using combinations of ECT with various drugs according to several experimental designs. For example, Abrams described Sager and Bird's study of 40 hospitalized patients given either 150 mg of imipramine a day or placebo and then given ECT 1 week later. They found that the ECT and imipramine combination resulted in the same number of ECT treatments and the same length of hospital stay but fewer relapses in the 6-month follow-up period.

Abrams also cited a study by Wilson of 36 hospitalized depressed women assigned to either ECT plus placebo, ECT plus 150–220 mg of imipramine a day, anesthesia plus imipramine, or anesthesia plus placebo. This study found no difference between ECT plus placebo versus ECT plus imipramine. However, ECT plus imipramine was superior to anesthesia plus imipramine and anesthesia plus placebo.

Another of Abrams' citations was Imlah's study of 150 patients divided into three groups: those given ECT plus 45 mg of phenelzine a day; those given ECT plus 75 mg of imipramine a day; and those given ECT plus placebo. This study noted no short-term differences between groups, but at 6 months the relapse rate was greater in the ECT plus placebo group. Abrams also cited two studies that found either diazepam or chlorpromazine in combination with ECT to have a possible depressing effect on ECT plus amitriptyline or ECT plus placebo, respectively. Abrams concluded that in depression, antidepressant drugs combined with ECT do not "reduce the number of treatments required, accelerate the treatment course, or enhance the final treatment outcome."

There appears to be no evidence of either good or bad synergistic effect in ECT plus the drugs mentioned above. However, the use of ECT with reserpine should be avoided because fatalities have been reported with this combination. Since tardive dyskinesia has been reported with some neuroleptics after relatively short periods of administration, their routine use should also be avoided. Combinations of tricyclics with ECT entail the risk of inducing a manic state; nevertheless, tricyclics may be used after successful ECT for maintenance of improved status. There may also be numerous instances in which drugs are required to manage agitation before or during the early stage of depression. If so, the medication should be withdrawn as soon as clinically feasible.

Schizophrenia

Studies of the use of drugs plus ECT in schizophrenia are too few to draw firm conclusions, but there is some evidence that the combination of ECT and chlorpromazine may be better than chlorpromazine alone, at least for a short period (3–4 weeks).

SUMMARY

The therapeutic value of ECT has been recognized for 40 years. Many technical improvements have been achieved during this time, including the reduction and modification of current, suppression of motor components of the convulsion, and use of unilateral nondominant ECT to mitigate the organic features of the post-shock period. Although no adequate theory exists to explain its mode of action, ECT has been of benefit to patients with psychotic depression, involutional melancholia, depression associated with brain disease, mania, schizo-affective disorders, and organic psychosis with excitement as well as to some patients with neurotic depression. It is contraindicated in psychosomatic disease, psychopathic personality, behavior

disorders of childhood, and the neuroses other than neurotic depression.

Studies of the comparative efficacy of ECT and drugs in depression suggest that ECT produced the fastest amelioration of symptoms; imipramine was next best, followed by amitriptyline, phenelzine, and isocarboxazid. ECT would be indicated for acutely suicidal patients and those who are most impaired by their illness. Results with placebo alone, it should be noted, have been substantial.

In schizophrenia, ataractic drugs plus psychotherapy and drugs alone gave results superior to those of either psychotherapy alone or milieu treatment; ECT-treated patients showed only moderate improvement. ECT has been successful in some cases in which drugs have failed.

Regarding combinations of ECT with drugs in depression, it would appear that, in general, antidepressives combined with ECT do not enhance the final outcome of treatment. The use of ECT with reserpine should be avoided because fatalities have been reported with this combination. Tricyclics may be used after successful ECT for maintenance of improved status.

Regarding combinations of drugs with ECT in schizophrenia, there are too few studies to draw firm conclusions; however, there is suggestive evidence that the combination of ECT and chlorpromazine may be better than chlorpromazine alone.

ECT and Ethical Psychiatry

BY CARL SALZMAN, M.D.

The author discusses the right to receive ECT and describes voluntary and involuntary patients for whom the treatment seemed both ethical and humane. The right to refuse ECT must be respected in competent patients. However, problems arise when patients' decision-making ability is compromised by their illness. Informed consent questions include how much and what type of information patients should receive and how much those with disordered cognitive functioning can be expected to understand. The author believes that ECT should be fully voluntary whenever possible and that a court-appointed guardian should make such treatment decisions for incompetent patients.

A GROWING controversy is crystallizing around the subject of ECT as an ethical mode of psychiatric treatment. Many physicians view ECT as accepted clinical practice, without ethical ambiguities (1), but others (2), supported by some patients'-rights advocates (3), would call for its abolition.

Questions regarding the ethics of ECT arise from a number of sources, including: 1) the physically invasive nature of the procedures, 2) the bad reputation ECT has acquired as a result of earlier, unmodified treatment methods, and 3) the potential for severe neurological side effects. For these reasons, there is justified concern about the potential abuse of ECT. Such problems, however, must be separated from ethical concerns that attend the legitimate use of ECT. These ethical problems are 1) the right to receive ECT, 2) the right to refuse ECT, and 3) the nature of informed consent about ECT and its potential hazards. These concerns, which are shared with many other areas of psychiatric treatment, are often difficult to resolve because ECT is used primarily for severely ill patients, who may not be able to assist in the decision-making process regarding their treatment.

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Salzman is Assistant Professor of Psychiatry and Co-Director, Psychopharmacology Research Laboratory, Harvard Medical School and Massachusetts Mental Health Center, 74 Fenwood Rd., Boston, Mass. 02115.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-12279 from the National Institute of Mental Health.

THE RIGHT TO RECEIVE ECT

The most radical critics of ECT reject the notion that it has any therapeutic benefits. Others believe that whatever small benefit it might have is far outweighed by the attendant hazards. However, if one accepts the sizable body of evidence suggesting that ECT is a rapid and relatively safe form of treatment for severe affective illness, then ethical issues are cast in a different perspective. One must consider whether it is a physician's ethical right to *refuse* an effective treatment. Consider the following clinical vignette.[1]

> A 49-year-old woman was voluntarily hospitalized with her third severe depression in 7 years. Her depressive symptoms included severe early morning insomnia, anorexia and weight loss, and an inability to concentrate. The latter symptom was especially troublesome since the patient was a concert violinist who had become unable to perform because she could not concentrate on her music. Previous treatment with ECT at other institutions had offered rapid relief and a return of her ability to perform. The patient refused antidepressant medication, which had made her more agitated in the past, and requested ECT. She denied memory loss from her previous treatments.

This patient responded to eight treatments without memory loss or confusion and returned to an active teaching and performing career. Would it have been ethical to withhold this therapy from a consenting patient or to use it only as a last resort when we had evidence that her condition would probably improve rapidly following ECT administration?

The ethics of withholding ECT are of particular concern for the patient who has not responded to other forms of therapy or who, because of medical illness, cannot safely take therapeutic doses of standard antidepressants. Consider also the patient who, for professional or personal reasons, cannot financially afford the 4–6 weeks that may elapse before therapeutic blood levels of chemical antidepressants are reached and who must be returned to his/her job or family as soon as possible. Should not such patients have the voluntary right to ECT? Is it not more ethical for the psychiatrist to consider the most rapid and safe form of antidepressant therapy for such patients, i.e., ECT? The following case vignette is illustrative.

> An 82-year old man with a history of two heart attacks, active diabetes mellitus, and a fluctuating cardiac ar-

[1] This clinical vignette, like the others in this paper, describes a real patient whose identity is markedly disguised.

rythmia was admitted on a voluntary basis because of severe depression accompanied by insomnia, an 11.4-kg weight loss, constipation, and dehydration that had resulted in serious electrolyte imbalance and decreased renal function. Because of the severe medical complications, the patient was not medically cleared for chemical antidepressant therapy but was cleared for ECT and anesthesia. An internal medicine consultant expressed the opinion that the patient was in danger of another heart attack or potentially fatal cardiac arrythmia if the symptoms of his depression (particularly the anorexia, as well as the insomnia) were not rapidly alleviated.

This patient responded after only six treatments and "seemed like a new person," according to his family. If one accepts the available data that ECT is a useful treatment for certain forms of affective illness and that it is sometimes less hazardous than doing nothing or using antidepressant drugs or long-term hospitalizations (or psychotherapy), then it would seem an ethical necessity to offer ECT to the consenting voluntary patient.

The right to treatment is most often associated with involuntary hospitalization. In the case of *Wyatt v. Stickney* the courts ruled that a patient cannot be confined involuntarily if he/she is not offered treatment (4–6). What if the patient is involuntarily hospitalized with a severe depression? The ethical problems of considering ECT for such a patient are illustrated by the following example.

The patient, a 67-year-old man, had a 5-month history of progressive weight loss, insomnia, and increasing suicidal preoccupation. He lived alone and prepared his own meals, and a neighbor had become concerned when she had not seen him for several days. With police assistance, he was discovered lying in his own waste; his body was covered with bed sores from excoriation and immobility. He was nearly mute, delusional, and clearly unable to care for himself. After medical treatment he was involuntarily hospitalized for treatment of a psychotic depression. His medical condition prohibited chemical antidepressants. He was unable to get out of bed and barely able to talk, so he could not participate in the therapeutic life of the ward community or in any type of psychotherapy. He was considered to be a psychiatric emergency.

Although few would disagree that this patient was severely ill and in need of care, he clearly had a right to be released from involuntary hospitalization if he could be offered appropriate treatment. The decision to offer ECT treatment was ethical, humane, and well within his rights as a patient. Beresford (7) has suggested that "involuntary patients who are not offered ECT for their psychotic depression may later contend that the hospital was negligent in omitting this medically indicated and highly effective treatment."

THE RIGHT TO REFUSE ECT

The ethical problems associated with ECT grow more complex when one considers a patient's right to refuse ECT. This right to refuse treatment, i.e., to decide one's own destiny, was well expressed by the 19th century British philosopher John Stuart Mill (8):

Considerations to aid his judgment, exhortations to strengthen his will, may be offered to him, even obtruded on him by others; but he, himself, is the final judge. All errors which he is likely to commit against advice and warning, are far outweighed by the evil of allowing others to constrain him to what they deem his good. . . . But neither one person, nor any number of persons, is warranted in saying to another human creature of ripe years, that he shall not do with his life for his own benefit what he chooses to do with it. He is the person most interested in his own well-being: the interest which any other person except in cases of strong personal attachment, can have in it, is trifling. . . . (8, p. 273)

More recently, Szasz (9) reminded us that patients have a right to self-determination, including a right to refuse treatment. The right to refuse ECT, like the right to refuse psychosurgery or other treatments, is a civil liberty that must be protected.

The ethics of considering ECT for nonconsenting patients involve the concept of *parens patriae* or psychiatric paternalism, i.e., the belief that the psychiatrist knows better than the patient what is good for the patient's health. Here we must consider the peculiar dilemma that confronts all psychiatrists: the patient's ability to make a rational decision about his or her own well-being is sometimes compromised by the nature of the disorder for which the treatment is indicated. This may be the case when ECT is being considered for treatment of psychotic depressive disorders. The following case vignette raises such an issue:

A 69-year-old man with a history of depressions was referred for hospitalization because of severe depression. The patient was agitated, pacing, wringing his hands, and crying "Oh, my God" over and over. He refused voluntary hospitalization, stating that his case was hopeless because his intestines and brain were rotted with cancer. This was untrue. When confronted with evidence of his normal physical functioning, the patient groaned that the cancers which were rotting his body were punishment for past sexual sins; the doctors' failure to perceive the cancers was dismissed as incompetence. For the next three weeks of hospitalization his delusions became even more fixed, and he refused food as well as any form of treatment.

This patient was given ECT after a court hearing at which he was judged incompetent to care for himself. A legal guardian was appointed to sign permission for the treatment. The depression lifted after 10 ECT treatments, and the patient left the hospital quite grateful for the help he had received. He stated he was glad that he had been treated against his will because "That wasn't the real me talking when I was sick."

What if the patient has an illness that is known to respond to ECT but is competent and continues to refuse the offer of treatment despite personal suffering as

well as the anguish of a concerned family and community? This situation, which is one of the most ethically precarious in psychiatry, is illustrated by the following brief case report:

> A 58-year-old divorced woman had several voluntary admissions to the hospital during a 6-month period. Each hospitalization was preceded by a brief stay in a medical hospital where she was treated for inanition, multiple self-inflicted skin excoriations, severe insomnia, and agitation. She would regularly visit many of the better staffed university hospital emergency rooms in Boston with multiple medical symptoms; all physical examinations were within normal limits. A diagnosis of recurrent unipolar depression had been made during a previous admission, and the patient was started on tricyclic antidepressant medication. During the ensuing months, several different tricyclic medications as well as a trial of monoamine oxidase inhibitors and lithium carbonate failed to alter her symptoms or suffering. She consistently refused ECT. She was judged to be nonpsychotic and not commitable by virtue of her ability to feed, clothe, house, and protect herself.

This patient did *not* receive ECT, even though the hospital staff tried to help her understand that without the treatment her suffering might worsen. Is the cost to the patient of declining health, as well as possible cost to a family or community, also part of the ethical decision to be made by the psychiatrist? I believe that in such cases the patient's wish not to be treated must be respected, despite pressures from family, friends, or community. Although it is painful for us to watch a patient suffer or even grow more symptomatic, we cannot force treatment on a competent nonconsenting person. We must, in these cases, relinquish the role of *parens patriae* in order fully to protect patients' rights.

Stone (10) has suggested that at a full judicial hearing a third-party decision maker in the person of a judge be required before ECT is administered to a protesting patient. He adds that "other third parties such as guardians, relatives, patient rights committees or other physicians not on the hospital staff will not insure the patient's civil liberties." He suggests a two-step procedure: a preliminary judicial hearing at which it is decided whether or not the observation, diagnosis, and preliminary treatment have been appropriate, and a second hearing, with the patient represented by counsel, in which parts of the treatment plan to which the patient objects are dealt with. Although such a policy may help safeguard patient rights, the essential ethical dilemmas are still unanswered. Does a psychiatrist have the right to do more than offer treatment? What is the psychiatrist's role with a patient whose ability to make health care decisions may be compromised by the symptoms for which the treatment is indicated?

INFORMED CONSENT FOR ECT

The last of the ethical dilemmas concerns the issue of how much information is necessary for a patient to make an informed decision about having ECT. Clearly, informed consent is an essential prerequisite for ECT. The dilemmas arise in 1) determining how much information must be given to ensure that consent is "informed," without scaring away the patient, and 2) establishing how much can be understood by patients with disordered cognitive functioning. In recent years, for example, the question of permanent disabling memory loss following ECT has become a concern. A thoughtful article in *The New Yorker* (11) recounts the case of a highly intelligent professional woman who, after being treated with a standard course of unilateral, nondominant temperoparietal ECT for a mid-life depression, became unable to resume her job as a result of alleged permanent memory loss (objective memory testing apparently was not performed). Although post-ECT amnesia has generally been demonstrated to be transient, this report raises the possibility that in rare or occasional instances the patient may experience memory loss as permanent. Is there sufficient evidence about such permanent memory loss to require psychiatrists to inform their patients of this possible consequence of ECT? At what level of statistical frequency does it become necessary to mention such a risk to a patient? Does the sharing of such information constitute a risk in itself?

It is hard to imagine that any patient who has been fully informed of the possibility of permanent, near-total memory loss would consent to such a procedure. If patients who might benefit from ECT are frightened away, have we done them a service? Ledensohn (12) notes that in discussions of the possible risks of ECT the patient and family must also be cautioned about the possible risks of not receiving ECT, such as suicide. Stone (10) noted that very large doses of potentially toxic medication, restraints, or maximum security measures may be necessary to protect the life of an acutely suicidal patient who does not receive ECT. Krouner (13) has reviewed and commented on the great variability among the different state laws regarding informed consent and ECT. State courts have had difficulty deciding how much information is helpful to a patient facing ECT, and decisions have ranged from no informed consent to the requirement of reasonable and recognized risks.

An even more difficult question involves the capacity of a severely ill patient to be informed at all. Consider the following case.

> A 52-year-old fully employed woman with a long history of recurrent depressions was voluntarily hospitalized with a psychotic depressive illness. She agreed to ECT without seeming to pay attention to the explanations of the treatment. After reading and signing the informed consent form, the patient remarked, "It doesn't make any difference anyway because it is all over for me; I am dead." This voluntary patient would probably have consented to any procedure. Did she truly understand the treatment—its effects and side effects—for which she gave permission?

To varying degrees, psychotically depressed patients may be incapable of fully appreciating what they are being told; they may be equally incapable of making an appropriate decision on the basis of such information. May we ethically treat them on the basis of such consent?

COMMENT

On the basis of available evidence, ECT has a legitimate clinical use for certain patients. It is neither a panacea nor a sadistic intrusion on personal liberty. Because patients for whom ECT is indicated often are severely ill, ethical dilemmas can arise regarding its use. The following guidelines are offered to help ensure that patients' rights, as well as concerns related to health, are respected and protected:

1. ECT should be given whenever possible as a fully voluntary procedure.
2. In cases of legal incompetence or when patients are unable to give informed consent, a court hearing should be convened to appoint a legal guardian for the patient. This guardian must act on behalf of the patient, not the psychiatrist or hospital, and decide about ECT as the patient would if he or she were competent to decide about health care as well as about civil rights. The guidelines suggested by Stone are excellent (10).
3. Information given to obtain informed consent should include the possibility of increased risks when there is concurrent medical pathology or dementia. The potential for memory loss should be discussed with the patient in advance, although it is reasonable to reassure the patient that on the basis of available evidence and clinical experience, memory loss is usually transient. The risks of not having ECT should also be explained, i.e., the risks of no treatment or alternative somatic therapy. Informed consent for ECT must be obtained independently from other hospital consent forms *before* the first treatment is given.

Although a patient's right to receive or not receive ECT can be protected, ultimately the public and the psychiatric profession must decide whether they believe ECT to be therapeutic or harmful. With increased cooperation among psychiatrists, lawyers, and civil libertarians, research can continue to evaluate the future role of ECT in psychiatry. Such cooperation rather than antagonism can help to establish a better set of ethical guidelines for the treatment as well as protection of patients' health and civil rights.

Shock Treatment, Brain Damage, and Memory Loss: A Neurological Perspective

BY JOHN FRIEDBERG, M.D.

The author reviews reports of neuropathology resulting from electroconvulsive therapy in experimental animals and humans. Although findings of petechial hemorrhage, gliosis, and neuronal loss were well established in the decade following the introduction of ECT, they have been generally ignored since then. ECT produces characteristic EEG changes and severe retrograde amnesia, as well as other more subtle effects on memory and learning. The author concludes that ECT results in brain disease and questions whether doctors should offer brain damage to their patients.

A 32-YEAR-OLD WOMAN who had received 21 ECT treatments stated 5 years later,

> One of the results of the whole thing is that I have no memory of what happened in the year to year and a half prior to my shock treatments. The doctor assured me that it was going to come back and it never has. I don't remember a bloody thing. I couldn't even find my way around the town I lived in for three years. If I walked into a building I didn't even know where I was. I could barely find my way around my own house. I could sew and knit before, but afterward I could no more comprehend a pattern to sew than the man in the moon. (1, p. 22)

By 1928, 10 years before the introduction of electroconvulsive therapy, it was known that accidental death by cardiac arrest could result from as little as 70 to 80 milliamperes in the human (2). It was also known in this early period that voltage applied to the head, as in legal electrocution, produced hemorrhage and rupture of cranial contents. Ugo Cerletti (3) demonstrated that electricity in the range of 100 volts and 200 milliamperes is rarely fatal when the current path is confined to the head, but does evoke a grand mal seizure marked by a stereotyped succession of events. A tetanic muscular contraction, the "electric spasm," is followed after a latency of seconds by unconsciousness, a high voltage paroxysmal spike and sharp-wave discharge, and a clonic convulsion. Upon recovery of consciousness the subject is left with a transient acute brain syndrome, a high likelihood of permanent brain damage, and greater retrograde amnesia than is seen in any other form of head injury.

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla. May 10–14, 1976.

Dr. Friedberg is a third-year resident, Department of Neurology, University of Oregon Medical School, Portland, Ore. Address reprint requests to 1120 N.W. 25th Ave., Portland, Ore. 97210.

The author thanks Mrs. Marilyn Rice for her assistance in assembling references.

BRAIN DAMAGE IN EXPERIMENTAL ANIMALS

Before examining the premise that ECT damages human brains, a brief discussion of the lesions produced in animals by electrically induced convulsions is worthwhile. The many reports on this subject indicate that petechial hemorrhages scattered throughout both white and gray matter and concentrated in the path of the current are the most consistent finding. If animals are sacrificed after a delay of days or weeks following a convulsive series, hemosiderin pigment in phagocytes remains as evidence of vascular insult. Proliferation of glial cells, neuronal changes, and dropout are also commonly reported.

In 1938, the year of the first use of ECT on a human being, Lucio Bini, Cerletti's collaborator, reported "widespread and severe" brain damage in dogs with mouth to rectum electrode placement (4). At least seven subsequent animal studies employing conventional cranial electrodes supported his findings (5–11). These culminated in the exhaustive controlled experiment by Hans Hartelius in 1952 (12). This researcher found discernible vascular, glial, and neuronal changes in cats subjected to a maximum of 16 shocks. The animals were not paralyzed but were protected from physical injury during the seizure. Damage was slight but consistent, and the author concluded: "The question of whether or not irreversible damage to the nerve cells may occur in association with ECT must therefore be answered in the affirmative." Furthermore, by examination of unlabeled slides alone Hartelius was able to correctly recognize 8 of 8 slides from shocked animals as well as 8 of 8 controls. Although he considered many of the vascular and glial changes to be reversible, there was no mistaking the brain of a shocked animal for that of a control.

Since that time, ECT in humans has been modified through the use of oxygen and muscle paralysis to reduce the incidence of bone fractures. Although it is believed that these modifications also reduce brain

damage, there are no animal studies to support this idea. On the contrary, recent work in England by Meldrum and associates (13, 14) on status epilepticus in primates suggests that the overexcited neuron by itself may be an important factor in seizure damage, especially in the hippocampus.

HUMAN BRAIN DAMAGE

Let us turn now to the neuropathological findings in humans who died during or shortly after ECT. As in lower animals, bleeding is the most frequent nonspecific tissue response to injury and the one seen most often after electric shock. The first autopsy study in this country revealed brain damage identical to that seen in experimental animals. Alpers and Hughes (15) described the brains of 2 women who had received 62 and 6 shocks, respectively. The first woman's seizures had been suppressed by curare. Both brains showed hemorrhagic lesions around small blood vessels, rarefaction of tissue, and gliosis.

Throughout the 1940s similar reports continued to call attention to brain changes after ECT, including cases in which oxygen and curare had been administered (16). In 1948 Riese (17) added 2 more autopsy studies to the growing list and commented, "In all observations of sudden death after electric shock reported so far, petechial hemorrhages, cellular changes and some glial proliferation stand out prominently, as an almost constant whole."

Pathologists were especially interested in cases that discriminated between the direct effect of electricity and the mechanical and hypoxic effects secondary to convulsive motor activity. In 1953 Larsen reported on a 45-year-old man who had been given 4 electroshocks in the course of 5 days. The ECT did not induce any convulsions. The subject died from pneumonia 36 hours after the fourth electroshock. At autopsy fresh subarachnoid hemorrhage was found in the upper part of the left motor region—"at the site where an electrode had been applied" (18).

In 1957 Impastato summarized 254 electroshock fatalities. Brain damage was the leading cause of death in persons under 40 years of age, and nearly one-fifth of all cerebral deaths were hemorrhagic (19).

Some physicians were alarmed by the evidence of human brain damage. In 1959 Allen reported 18 cases in which he had found signs and symptoms of neurological sequelae following ECT. He concluded, "It is probable that some damage, which may be reversible but is often irreversible, is inseparable from this form of treatment," and called for "more serious consideration" of the entire procedure (20).

In 1963 McKegney and associates (21) reported the case of a 23-year-old man who became comatose 15 minutes after a single shock. The significance of this case was twofold: first, a complete physical and neurological examination was reportedly normal prior to ECT, and second, the ECT technique was contemporary and impeccable. The patient had received .6 mg of atropine, 16 mg of succinylcholine (Anectine), and forced oxygenation pre- and post-shock. ECT parameters were conventional, i.e., 130 volts for .3 seconds. Four days later a brain biopsy showed diffuse degeneration of neurons with hyperplasia of astrocytes. The young man never regained consciousness and at autopsy 2 months later evidence of old hemorrhage was found in the brain. This was the last detailed report in the English-language literature.

The damaging effects of ECT on the brain are thoroughly documented. All told, there have been 21 reports of neuropathology in humans (22–36). It is interesting that, despite the importance of a negative finding, there has not been a single detailed report of a normal human brain after shock.

ELECTROENCEPHALOGRAPHIC EFFECTS OF ECT

Like other insults to the brain, ECT produces EEG abnormalities. Diffuse slowing in the delta and theta range, increased voltage, and dysrhythmic activity are seen in all patients immediately following a series of bilateral ECT and, according to Blaurock and associates (37), may persist more than 6 months in 30% of the cases. Such slowing suggests damage to the thalamus.

Sutherland and associates (38) showed that the side of the brain shocked with unilateral ECT could be predicted by double-blind assessment of EEG tracings.

The seizure thresholds of the hippocampus and other temporal lobe structures are the lowest in the brain; considerable interest has centered recently around "kindling," or seizure induction by subthreshold stimulation of these areas in animals (39). The induction of a permanent epileptic disorder following ECT in humans was first reported in 1942 and other reports followed (40).

MEMORY LOSS

ECT is a common cause of severe retrograde amnesia, i.e., destruction of memories of events prior to an injury. The potency of ECT as an amnestic exceeds that of severe closed head injury with coma. It is surpassed only by prolonged deficiency of thiamine pyrophosphate, bilateral temporal lobectomy, and the accelerated dementias, such as Alzheimer's.

After ECT it takes 5 to 10 minutes just to remember who you are, where you are, and what day it is. In the first weeks after a full course, retrograde and, to a lesser extent, anterograde amnesia are evident to the casual observer. But as time passes compensation occurs. As in other forms of brain injury, the subject is often oblivious to the residual deficit. Unless specific memories essential to daily living are discovered to be unavailable the victim may never know for sure the extent of memory loss. Unless sensitive tests for spon-

taneous recall of personal preshock data are employed, no one else will know either.

The memory loss following ECT generally follows Ribot's law for all pathological amnesias: the new dies before the old. This, of course, is the opposite of normal forgetting. Squire, however, has shown that the loss may extend to items learned more than 30 years before (41).

The effect of ECT on memory was common knowledge within a few years of its introduction. There were reports of persons who forgot they had children (42, 43), although most amnesias involved humbler matters, such as the woman who forgot how to cook familiar dishes (44) and another who couldn't remember her own clothing and demanded to know who had put the unfamiliar dresses in her closet (45). Some doctors dismissed these sequelae as trivial or transient, although one psychiatrist remarked that psychotherapy was useless in patients undergoing ECT because they couldn't remember "either the analyst or the content of the analytic sessions from one day to the next" (46).

Numerous such case reports finally led to a definitive study of the effects of ECT on memory by Irving Janis in 1950 (47). He found that all 19 subjects in a controlled prospective investigation had significant memory loss 4 weeks after ECT, compared to negligible losses among control subjects. He also noted that these losses may involve events of early childhood dating back 20 to 40 years, with the more recently encoded memories being the most vulnerable. Patient E, for example, a 38-year-old woman, had told Janis in an interview prior to ECT that thyroid medication had caused heart palpitations and panic which led to her admission to the psychiatric hospital. When asked after a course of 10 shocks if she had ever taken thyroid she responded, "I don't think so."

In the late 1940s, when the enthusiasm for ECT seemed to have passed its peak (48), Lancaster and associates (49) advocated the use of unilateral nondominant ECT in treating patients who earn their livelihood with retained knowledge. In this variant the current path and most of the damage is confined to the nonverbal side of the brain, usually the right hemisphere. This exploits the well-known neurological phenomenon of anosognosia, or denial, that is associated with right-hemisphere lesions—victims can't verbalize their difficulties. They complain less. Cohen and associates (50), however, using design-completion tests, proved that shock to the right hemisphere produces its own kind of memory loss—visual and spatial. Inglis found in 1970 (51) that the effects of unilateral ECT were comparable to those of right and left temporal lobectomy, with identical impairment of memory and learning.

Recently there has been a good deal of human experimentation in a futile effort to find electrode placements that eliminate amnesia. As the use of ECT has shifted from state hospitals to private practice, the literature has focused more and more on memory loss. Although some studies have purported to show improvement of learning ability after ECT, not one used sham ECT as a control and few used any controls at all.[1]

In regard to more general intellectual ability, a study in 1973 (54) showed that the performance on the Bender Gestalt perceptual motor test of 20 institutionalized subjects who had received 50 or more ECT treatments 10 to 15 years before testing was significantly impaired compared to the performance of 20 carefully matched control subjects who had not received ECT. The authors inferred that ECT had caused permanent brain damage.

MECHANISM OF ACTION OF ECT

The mechanism of action of ECT can now be summarized on the basis of evidence accumulated since its introduction. Penfield and Perot showed in the 1950s that memory traces may be evoked by direct electrical stimulation of the temporal lobe cortex, and nowhere else (55). Scoville and Milner (56) discovered that bilateral hippocampal resection utterly abolished the ability to remember any new material, resulting in a catastrophic inability to learn. From numerous studies of the neuropathology of the amnestic-confabulatory syndrome of Korsakoff it is known that the mammillary bodies, the dorsal median nuclei of the thalamus, and the gray matter surrounding the third ventricle and aqueduct are essential to the general memory process. All of these critical brain structures are just beneath the thin squamous plate of the temporal bone, within seven centimeters of the electrodes, in the direct path and highest density of the current during ECT.

CONCLUSIONS

From a neurological point of view ECT is a method of producing amnesia by selectively damaging the temporal lobes and the structures within them. When it was first introduced it was only one of several methods of producing brain damage employed in psychiatry, including insulin coma (1927), camphor and pentylenetetrazol (Metrazol) injections (1933), and prefrontal lobotomy (1935). It is the only such method from that era still used on a large scale. It is highly unlikely that ECT, if critically examined, would be found acceptable by today's standards of safety.

From a neurological point of view ECT produces a form of brain disease, with an estimated incidence of new cases in the range of 100,000 per year (57). Many psychiatrists are unaware that ECT causes brain damage and memory loss because numerous authorities and a leading psychiatric textbook (58) deny these

[1] Sham ECT, an essential control technique, has been employed in only two studies, which were tests of efficacy, not tests of memory loss. Neither study showed any superiority of ECT over the control treatment (52, 53).

facts. Others, who know of its effects, argue that the interruption of unpleasant states of mind is worth the damage. Some are beginning to give the client a truly informed choice, although most state laws still allow ECT to be imposed if the doctor feels that "good cause" exists.

Assuming free and fully informed consent, it is well to reaffirm the individual's right to pursue happiness through brain damage if he or she so chooses. But we might ask outselves whether we, as doctors sworn to the Hippocratic Oath, should be offering it.

Current Perspectives on ECT: A Discussion

BY FRED H. FRANKEL, M.B.CH.B., D.P.M.

MY COMMENTS about each of the preceding papers on ECT reflect my personal views and not those of the former Massachusetts Task Force on ECT (1) or the American Psychiatric Association's Task Force on ECT. Space limitations preclude a complete discussion of each of the papers, but I will attempt to address at least some of their important or controversial points.

ECT: A NEUROLOGICAL PERSPECTIVE

In my view, Dr. Friedberg has weakened his position by the manner in which he has gathered the evidence to support it. The questions he raises are relevant; they have been asked by many others. However, he has attempted to answer them with data that have been carelessly culled from the literature and frequently reported inaccurately.

Dr. Friedberg's evidence against ECT is arranged in four main sections. He reports on the neuropathological findings in experimental animals subjected to electrically induced convulsions, and in humans who have died during a course of ECT or within weeks or months afterward. He then reports studies and subjective accounts of memory loss and, finally, EEG changes. He concludes that "from a neurological point of view ECT is a method of producing amnesia by selectively damaging the temporal lobes and the structures within them." He states that "ECT produces a form of brain disease" of epidemic proportions and asks why doctors, who are sworn to the Hippocratic Oath, are offering it.

Dr. Friedberg has listed 58 references in his article. I have examined 25 of these and selected those which seemed especially relevant to his argument.

In presenting his evidence for brain damage in animals exposed to electrical currents, Dr. Friedberg states: "In 1938, the year of the first use of ECT on a human being, Lucio Bini, Cerletti's collaborator, reported 'widespread and severe' brain damage in dogs. At least seven subsequent animal studies confirmed his findings." The following quotation is from the Bini reference:

> We have so far employed exclusively the method of Viale, which consists of passing the street current (120 volts) for a very short time (1/15 to 1/20 second) through the entire body of the animal with one of two electrodes (carbons from a voltaic arc) in the mouth and the other in the rectum.
>
> With this method we succeeded in producing constantly typical epileptic attacks in dogs. During the passage of the current the animal howls and has a violent tonic spasm with opisthotonus which lasts several seconds after the circuit is opened. Then there appear frequent and violent generalized tonic and clonic convulsions with foaming at the mouth, biting of the tongue, and incontinence of urine and feces. The duration of this second phase varies from 1–2 minutes. There follows a comatose state with complete muscular relaxation, absence of corneal and pupillary reflexes and stertorous breathing. In a short time the

Revised version of a presentation at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Frankel is Head, Adult Psychiatric Unit, Beth Israel Hospital, 330 Brookline Ave., Boston, Mass. 02215. He is also Associate Professor of Psychiatry, Harvard Medical School, Boston, Mass.

> animal returns to its normal state, so that after a few minutes new seizures may be induced.
>
> The alterations found by us in the nervous systems of these dogs were widespread and severe. (2, p. 173)

Bini did not state how many seizures were induced, but clearly they were multiple, and the current was applied along the course of the entire body, with one electrode in the mouth and the other in the rectum. I cannot seriously believe that Friedberg considers this to be the customary method of administering ECT, and yet he has quoted Bini's report as if the procedures described were analogous to those used today. Furthermore, there is no mention of the method of sacrificing the animals and no consideration of the fact that anoxia or trauma could have contributed to Bini's findings in the central nervous system.

Dr. Friedberg then claims that seven subsequent animal studies confirmed Bini's findings. In doing so, he has revived the controversy that waxed during the 1940s. I have examined five of these references. Far from confirming the point, two (3, 4) unequivocally disagree with the idea that widespread and severe damage results from electrically induced convulsions in animals, *unless* the current is abnormally prolonged or administered repeatedly or in excess of that used in ECT.

The three other studies I examined are the well-publicized reports by Alpers and Hughes (5), Heilbrunn and Weil (6), and Neuberger and associates (7). They all reported damage to the central nervous system. However, a detailed study of their comments revealed less than the well-established evidence that Friedberg claims supports his argument. Alpers and Hughes (5) made no mention of the voltage used. Heilbrunn and Weil (6) reported an electrically produced convulsion in 28 rabbits, 16 of which were paralyzed in the lower limbs, bladder, and rectum after the first few shocks. Nonetheless, they were then still shocked daily for several days before being sacrificed and examined. The size of the electrodes and the current used were equivalent to those employed in ECT and were totally disproportionate to the size of the rabbit's brain. In no way can that study be considered relevant to the current administration of ECT. Neuberger and associates reported that although they found pathological changes in the brains of the animals studied, these changes "were not to be regarded as serious."

Space limitations preclude a detailed examination of the other contradictions and inconsistencies that unfold during an examination of Dr. Friedberg's bibliography, but it is necessary to study a few of them in some detail if we are to place his paper in perspective. He has published widely and has worked hard at trying to influence public opinion. He has revived the controversy of the 1940s and 1950s and maintains that the introduction of anesthesia, oxygenation, and muscle paralysis since that time has in no way diminished the risks of ECT. He appears to base his position on the following two principal assertions: 1) he argues as if the damage caused by a single seizure must be as great as that caused by large numbers of seizures concentrated within a brief period of time, and 2) he states emphatically, "Although it is believed that these modifications [of ECT, namely, the use of anesthesia, oxygenation, and muscle paralysis] also reduce brain damage, there are no animal studies to support this idea."

Dr. Friedberg's next sentence is perhaps the most misleading. "On the contrary, recent work in England by Meldrum and associates [8, 9] on status epilepticus in primates suggests that the overexcited neuron by itself may be an important factor in seizure damage, especially in the hippocampus."

The recent reports by Meldrum and associates deal with the effects of prolonged seizure activity in baboons in an attempt to understand the effects of status epilepticus in humans. In the first study (8), seizures were precipitated in 8 anesthetized adolescent baboons by injections of the convulsant bicuculline. The animals were artificially paralyzed and oxygenated, and the seizure activity was recorded on EEG. Physiological factors were monitored. The activity lasted from 3¼ to 7½ hours in 7 of the 8 animals. The eighth animal experienced a period of 13 minutes of seizure activity and then, after a second injection of the convulsant almost 3 hours later, experienced an additional hour and 49 minutes of seizure activity. The animals were sacrificed during or shortly after the seizures and the brains examined. There were ischaemic cell changes in the brains of the first 7 animals, but not in the brain of the eighth animal, which had experienced only a little over 2 hours of seizure activity. Meldrum and associates (8) noted that in comparison with their previous work, the presence of peripheral motor paralysis and artificial respiration greatly reduced the severity of the systemic changes and modified the pattern of epileptic brain damage.

How do these comments fit in with Dr. Friedberg's assertion that there are no animal studies to support the idea that modifications of ECT reduce brain damage? In support of his position he reported, out of context, a suggestion by Meldrum and associates that the overexcited neuron by itself may be an important factor in seizure damage. The overexcited neuron alluded to in the original paper refers to the neuron after excessive discharge and seizure activity lasting from 3¼ to 7½ hours, which is scarcely comparable to the neuronal activity associated with a single session of ECT.

In a subsequent study by Meldrum and associates (9), 13 baboons were submitted to similar experiments using the convulsant allylglycine. Five animals developed status epilepticus, and in the other 8 animals, 6–63 seizures occurred in a period of 2–11 hours. Progressive hypoglycemia and hyperpyrexia occurred with the recurrent seizures. The animals were sacrificed at varying stages up to 6 weeks after the experience, and the brains examined. The animals that had had 6–26 seizures over a period of several hours showed *no* pathological sequelae. The animals that had had more than 26 seizures, or status epilepticus,

showed varying degrees of ischaemic cell change and neuronal loss with gliosis in the neocortex and lesions in the hippocampus. Meldrum and associates felt that the relative importance of the various physiological changes associated with the repeated seizures could not be definitively established, and they concluded that the effects of hypoglycemia, hyperpyrexia, reduced oxygenation, and impaired cerebral perfusion were probably additive in causing the damage.

Dr. Friedberg's discussion of brain damage found at autopsy on patients who died during or after ECT contains an equally unconvincing body of evidence. It leaves the reader wondering, in many instances, about the true nature of the disease for which ECT had been given, how carefully neurological disease had been excluded prior to administration of ECT, and what role cardiovascular and renal disease had played in causing the pathology found at autopsy. McKegney and Panzetta's report in 1963 (10) of a 23-year-old man who became comatose 15 minutes after his first course of ECT and died 2 months later without having regained consciousness illustrates the point very well. The following material is from the original article:

> The patient, a 23-year-old, single, white male . . . was initially seen in the emergency department of a general hospital on Apr. 5, 1962 because of withdrawn and bizarre behavior. He had a long history of "emotional difficulty". . . .
>
> The medical house officer who first saw the patient . . . was unable to perform a complete physical examination since the patient seemed purposively to resist, giggling inappropriately at times, curling himself up and lying with his hands between his thighs. Psychiatric consultation at that time suggested the diagnosis of schizophrenic reaction, catatonic type, and the patient was admitted to the psychiatric unit.
>
> The patient remained essentially unchanged throughout the rest of the evening and the following day, lying in bed with his eyes closed. When called by name he would start and half open his eyes, but then close them quickly and turn his back on the examiner. . . . There were considerable posturing and unusual movements. A complete physical and neurological examination, performed on the second hospital day, was negative in all respects other than the behavior noted above. The axial temperature was 37° C; blood pressure 120/72; pulse 58 per minute and regular; respiration 16–20 per minute and regular.
>
> In order that the patient could be fed and more readily mobilized, he was given his first ECT on the morning of Apr. 7 (atropine .6 mgm., as premedication; anectine 16 mgm. intravenously; 130 volts for 0.3 seconds; forced breathing with oxygen pre and post ECT). (10, pp. 398–399)

It was soon apparent that the patient's post-ECT recovery was not normal. The patient died June 11, 1962, more than two months later, without ever deviating from his progressively deteriorating course. Brain biopsy showed diffuse degeneration of neurons with hyperplasia of astrocytes. At autopsy, old hemorrhage was found in the brain.

There are several interesting and challenging details of this case report not recounted fully here. I would nonetheless have hoped that Dr. Friedberg, as a neurologist, would have been sensitive to the neurologically salient points in the case. It is most unlikely that the subtle measurements that are part of a complete neurological examination were possible in a patient as uncooperative as this one; and the EEG and cerebrospinal fluid analysis and culture were carried out *after* the ECT, not before it. The diagnosis of catatonic schizophrenia is poorly supported by the information in the case history, and in my opinion the presence of organic brain disease had not been ruled out before the hasty use of ECT to control the patient's symptoms. In the absence of a clear diagnosis, the use of ECT to control symptoms is ill-advised.

Allusions in Dr. Friedberg's paper to several other articles fail to reflect the balanced view that the articles actually convey when read in the original. Interested readers should examine for themselves some of the studies to which he refers. The literature of that period is rich in reports expressing differing views. Dr. Friedberg either ignores them or, as I have indicated, quotes them erroneously.

His comments regarding memory loss after ECT, and EEG changes, are made with the same bold, sweeping strokes. There are occasional complaints of memory loss after ECT, but the results of unilateral electrode placement would not be regarded as a "futile effort" to remedy the problem. Dr. Friedberg would have us believe that because of damage to the right cerebral hemisphere after unilateral ECT, the improvements reported by patients are attributable to their denial of their illness and their inability to verbalize their difficulties. No one who has ever talked with patients and shared their relief and delight at feeling better and capable of a normal life after ECT can take Dr. Friedberg's assertion seriously, especially when 6–12 months later these patients are still functioning and feeling well.

None of my statements should be construed to mean that there are no unanswered questions regarding ECT. I believe there are many unsolved problems, as the other articles in this special section have attested. There is no reason to assume that we can induce large numbers of seizures with inpunity because less than 26 seizures in Meldrum and associates' baboons did not seem to be associated with cerebral damage. In addition, it is clear that there are insufficient data at this time from which to understand the occasional complaints of persistent memory disturbance after ECT. The APA Task Force on ECT, on which I serve, was established to weigh the evidence as carefully as possible and to assess realistically the cost/benefit ratio of ECT. There is no simple answer to the questions, and Dr. Friedberg's determination to present one has involved him in a report of the literature that is not only inaccurate and careless, but also somewhat indiscriminate. In addition, his reports of memory impairment have been gathered from people who answered his newspaper advertisement soliciting complaints. He

headed the advertisement, "Shock treatment is not good for your brain." He is, therefore, basing his conclusions regarding memory loss on a biased sample; in addition, he could have harmed the very people he claims to be helping by reinforcing the secondary gain provided by their amnesia and their overwhelming yet poorly understood anger.

It seems to me that Dr. Friedberg's personal opinions have been presented as scholarly decisions. He has directed them at stirring up emotions in an area already sorely in need of reasoned discourse and a serious effort to understand why, when ECT has brought relief to so many thousands of patients in the past, in some cases it has resulted in dissatisfaction and angry complaints. I hope that he will consider joining the ranks of those who aim to grapple with the issues by carefully and painstakingly sifting the evidence and concentrating on the facts.

ECT AND MEMORY LOSS

Dr. Squire presents a methodology for the understanding of ECT and memory loss that explores areas which have been especially challenging. By a system of comparisons among patients who received bilateral ECT, right unilateral ECT, or no ECT, and using tests that are quite ingenious in design, he found that memory recovers substantially by six to nine months after the completion of bilateral or right unilateral ECT, but that persisting memory complaints are not uncommon in individuals who have received bilateral treatment.

The risks to memory associated with unilateral treatment are markedly less than those associated with bilateral treatment, but the fact remains that some risk does exist. Clinical situations must be evaluated carefully. The benefits to be derived from the procedure must be weighed against its risks and the risks weighed against the discomfort or anguish of no treatment, the discomfort and even danger—especially in the older patient—of the side effects of antidepressant drugs, and the risk of suicide.

I would hope that Dr. Squire's studies will be replicated by others. Confirmation of his findings by other investigators will be reassuring and is, in fact, necessary. I find especially interesting his suggestion that bilateral ECT might itself lead to a lingering sense of memory impairment due to the fact that some individuals are more sensitive to subsequent failure to remember than others. Studies of differences in personality and cognitive style among those who are sensitive and those who are not might be helpful.

EFFICACY OF ECT IN AFFECTIVE AND SCHIZOPHRENIC ILLNESS

Dr. Greenblatt's paper conveyed the feeling of relief and dramatic uplift that attends the successful administration of ECT—not only for the patient who experiences the mood change, but also for the relatives and the psychiatrist. His statements remind us that ECT is and often has been prescribed by sincere people who are motivated to help their patients get better. The motivation to use ECT would have been dampened long ago had the treatment never promised, nor produced, successful results. The studies reported by Dr. Greenblatt bear testimony to the fact that for some forms of depression ECT is by far the most useful treatment. What is less obvious is why it does not always work when we expect it to and why it occasionally works with conditions for which it is considered to be only minimally effective.

Dr. Greenblatt proposes a protocol that the cautious may already be following, namely: "Imipramine or phenelzine is indicated for patients who are not acutely suicidal; if no improvement occurs after 3 weeks, ECT is indicated." While there are probably many physicians who would want to wait longer than three weeks, and others who would wait indefinitely rather than give ECT, there are those who believe that under some circumstances the use of ECT at the very beginning of the treatment procedure is justified. Would we agree that there are situations in which that might be the wisest clinical course?

In the treatment of atypical and reactive or neurotic depressions, the comparative value of ECT on the one hand, and medication plus psychotherapy on the other, has not been adequately studied. Nevertheless, we know that ECT is often administered in the presence of neurotic or reactive depression, with little documentation of the outcome or the cost. That practice has raised serious questions in some quarters. We need to bear in mind that definitive answers are not yet available regarding the value of ECT in depressive reactions that are often easily treated by skilled psychotherapy and/or medication.

MYTHS OF ECT

In Dr. Fink's rich commentary on ECT he points out that we do, indeed, know enough about ECT to state that the electric shock and convulsion per se are not essential for the treatment to be successful and that the length of the cerebral seizure has been shown to be related to the effectiveness of the treatment. Neither electric current nor a convulsion is central to the therapeutic process. Dr. Fink emphasizes, too, that we now also know that memory impairment is not essential for improvement and that ECT is not merely palliative in the treatment of depression.

He refers to the unknown biochemical changes that accompany and persist after ECT and offers the interesting conjecture that the central action of ECT is to elicit prolonged diencephalic stimulation. He points out that hypothalamic products affect behaviors related to the syndrome of depression. He also makes the interesting suggestion that in schizophrenia, ECT appears to have a related but different focus of action.

The clinical efficacy of ECT in schizophrenia appears to be less, and the number of seizures needed to effect a change, greater. He challenges the notion that the ECT process is unitary for all conditions, suggesting that it varies from one diagnostic entity to another.

These assertions and hypotheses are interesting, and they carry two important practical implications. The first is the need to examine the cost/benefit ratio in the consideration of a proposed treatment, and the second is the need for further studies on the outcome of treatment where the cost/benefit ratio is unknown because of insufficient data. We know that for selected populations, ECT has a cost/benefit ratio at least as good as that of other treatments. Those selected groups include patients with psychotic depressive states and those with acute schizophrenic symptoms in need of control. In all other conditions, including the use of ECT with children and adolescents, in maintenance treatment, in neurotic depressive states, and in chronic schizophrenia, the data are either minimal or insufficient. There is a cost to memory, reversible in the great majority of patients but apparently persistent, at least subjectively, in some. The data also show that subsequent seizures might be kindled in a small percentage of patients receiving ECT.

Under these circumstances, decisions to administer ECT cannot be taken lightly, even when no alternative treatment is available. When the effectiveness of ECT is less certain, or when it is used experimentally, it should be acknowledged as such and no effort spared to study the outcome.

Now, how can we communicate the complexity of these concepts to patients and relatives as we struggle with the subtleties of informed consent?

ECT AND ETHICAL PSYCHIATRY

Dr. Salzman has captured the absurdity of a system that demands informed consent from those who, although not disturbed enough to warrant involuntary admission to a hospital, are not well enough to understand the full implications of the procedure they are consenting to. Under these circumstances, fully informed consent is impossible. One could dwell for hours on the pros and cons of the concept of informed consent, but our task takes us directly to Dr. Salzman's two questions: 1) Does a psychiatrist have the right to do more than offer treatment? 2) What is the psychiatrist's role with a patient whose ability to make health care decisions may be compromised by the symptoms for which the treatment is indicated?

Our Hippocratic Oath demands, on the one hand, that any regimen we adopt shall be for the benefit of those who consult us; but the law, on the other hand, has been increasingly vocal in prescribing limits to our authority to do so. I think our responsibilities are nevertheless still clear. Regarding Dr. Salzman's questions, I believe we must do more than merely offer or suggest the treatment we believe to be the most effective. If we have any serious question about the patient's ability to understand the complexities of the situation, whether he be voluntarily or involuntarily admitted to a hospital, we have a duty to move the matter into the courtroom for the decision to be made there. I agree that the courts must decide on the competence of the patient to understand the issues. However, I am not as sanguine as Stone (11) and Salzman that the courts should be central to clinical decisions regarding diagnosis and treatment.

In discussing what he considers to be abuses of ECT, Dr. Salzman reports that several states have been prompted to enact regulations to control the practice of ECT. He believes such regulations to be useful and proper. I believe that while regulations are appropriate and, at times, indicated, legislative statutes have no place in the practice of medicine. They are subject to the whims and bargaining that are part of the political process and readily become rigid, resisting the modifications that are demanded by the discovery of new knowledge. However, local regulations are in a different category; government or semigovernment bodies that grant licenses to treatment facilities may occasionally have to help maintain standards of clinical practice, and at times it appears necessary that they do so. The Massachusetts Department of Mental Health, as a result of a task force report requested by then Commissioner Milton Greenblatt, developed a set of regulations that placed a ceiling on the number of sessions of ECT that could be administered to a patient within one year. Patients considered to be in need of additional sessions had to be examined by consultants and reported to the commissioner's office. Statistics attest to the fact that those regulations were capable of influencing clinical practice in the desired direction (12).

Perhaps we should be relieved that lawyers, legislators, and administrators are so eager to lighten our burden by making decisions for us. Would they were the wise ones to whom we could defer. However, their record over the past decade persuades me that systems developed to deal with patients not capable of informed consent are likely to fall wide of the mark if the sifting of clinical evidence is in the hands of nonclinicians. In my view, the clinical interests of the mentally ill will suffer irreparably unless the input of experienced and well-informed clinicians remains the pivotal point of the clinical decision.

Medical Histories of Delinquent and Nondelinquent Children: An Epidemiological Study

BY DOROTHY OTNOW LEWIS, M.D., AND SHELLEY S. SHANOK, M.P.H.

The authors studied the hospital records of 109 delinquent children and a matched comparison group of 109 nondelinquent children. The number, reasons for, and timing of hospital contacts significantly differentiated the delinquent from the nondelinquent children; perinatal difficulties did not. The authors hypothesize that an interaction of developmental factors and parental inadequacies accounts for the clustering of hospital contacts before age 4 and between ages 14 and 16 in the delinquent sample. They discuss the implications of their findings for prevention.

THE PURPOSE of this paper is to report the striking differences we found between delinquent and nondelinquent children with respect to the number, quality, and timing of medical problems. We will look at the relationship of accidents, injuries, and illnesses throughout childhood to social maladjustment. We will examine the emphasis in the literature on perinatal factors in the etiology of deviance and explore the importance of later medical events.

This study sprang from the clinical observation that many of the children referred to a juvenile court clinic had experienced multiple accidents, injuries, and illnesses. They had been hit by cars, fallen from roofs, and suffered serious physical trauma at the hands of relatives and peers. From a clinical standpoint, some of these injuries and illnesses seemed to have contributed to the children's inability to form appropriate judgments, assess reality, and control their behavior.

Dr. Lewis is Associate Clinical Professor of Psychiatry and Ms. Shanok is Associate in Research, Child Study Center, Yale University, New Haven, Conn. 06510.

This research was supported by grant 755-0371 from the Ford Foundation.

They had made frequent visits to the emergency room and clinics of one of the general hospitals in the community. On the other hand, relatively few of these children, according to their parents, had been the products of difficult pregnancies or deliveries, and almost all were reported to have had normal developmental milestones. Because we recognized that histories based on parental recollection alone were possibly unreliable we saw the need to study the question of medical histories more systematically.

THE LITERATURE

There is evidence that perinatal factors may have long-term effects on the adjustment of children (1–4). Whatever the limitations and questions raised by studies of perinatal effects, together they comprise an impressive body of knowledge. Although some authors have reported an association between neurological disease and delinquency (1, 5), those who have looked at the later medical status of delinquent children have reported few immediately obvious serious medical disorders (6, 7).

A few investigators, although they recognized that only a small percentage of delinquent children show flamboyant evidence of physical disorders, have speculated on the possible behavioral effects of what may appear to be minor physical disorders (8, 9). Gibbens reported that, although obviously serious head injuries such as encephalitis or skull fracture had occurred in only 1%–2% of the delinquents he studied, many delinquents did have histories of having sustained what seemed at the time of accident to be minor head injuries. Unwilling to dismiss these apparently trivial injuries, Gibbens speculated that "the effects of these minor head injuries and of special handicaps are very difficult to assess" (9, p. 1,087).

In studies of hospital records the psychological effects of separation have often been emphasized rather

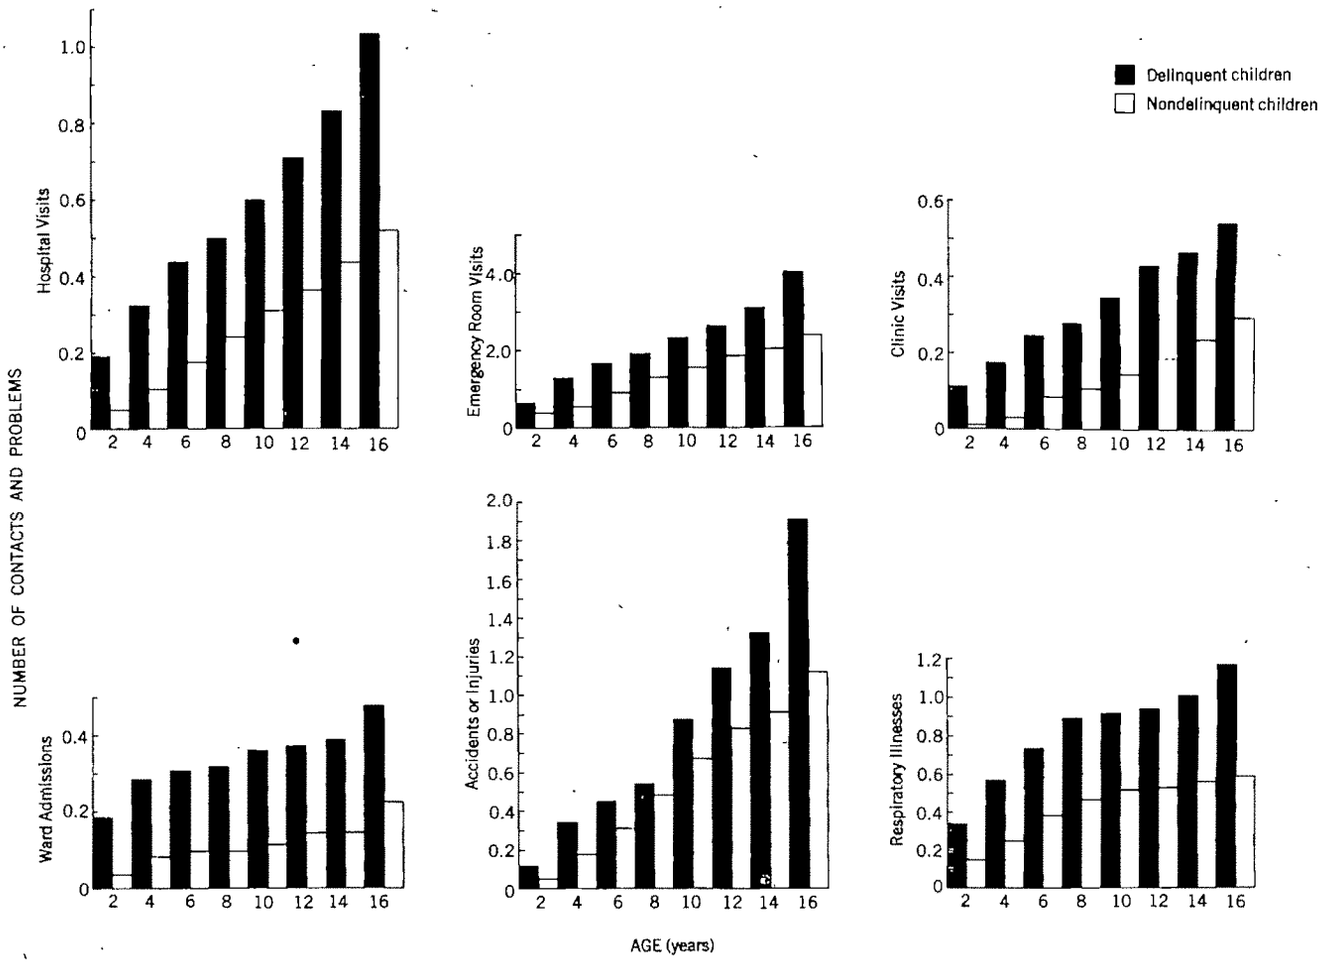
than the other possible meanings of hospital contacts (10, 11). The present study looks beyond questions of separation and uses hospital data to examine a possible interaction of medical, developmental, and familial factors contributing to delinquent behavior.

METHOD

Two groups of children were chosen for study: 1) a random sample of 109 delinquent children referred to the juvenile court but not to the court clinic and 2) a sample of 109 nondelinquent children from the New Haven area with demographic characteristics similar to those of the delinquent population. We decided to use a random sample of delinquent children instead of those referred to the court clinic (on whom our initial clinical observations were made) because of the likelihood that a clinic-referred sample would be biased toward physical pathology as well as psychopathology and therefore would not be typical of the general court population (12).

Although the juvenile court records did not always allow for accurate socioeconomic class assignment, it was generally recognized by court and clinic staffs that the great majority of delinquents were from the lower socioeconomic classes in the area. Thus the nondelinquent sample was chosen from a population of which 75% would have been classified as coming from classes IV and V of the general population according to the Hollingshead and Redlich scale (13).



Each of the 109 delinquent children was matched with a comparison child for age, sex, and race. Two-thirds of each sample were white; the other third were black. Two-thirds of each sample were boys; the other third were girls. At the time of the study the average age of both groups was 19 years. Because of the legal and ethical limitations on access to data about siblings of the index patients, it was not possible to include a comparison group of nondelinquent siblings.

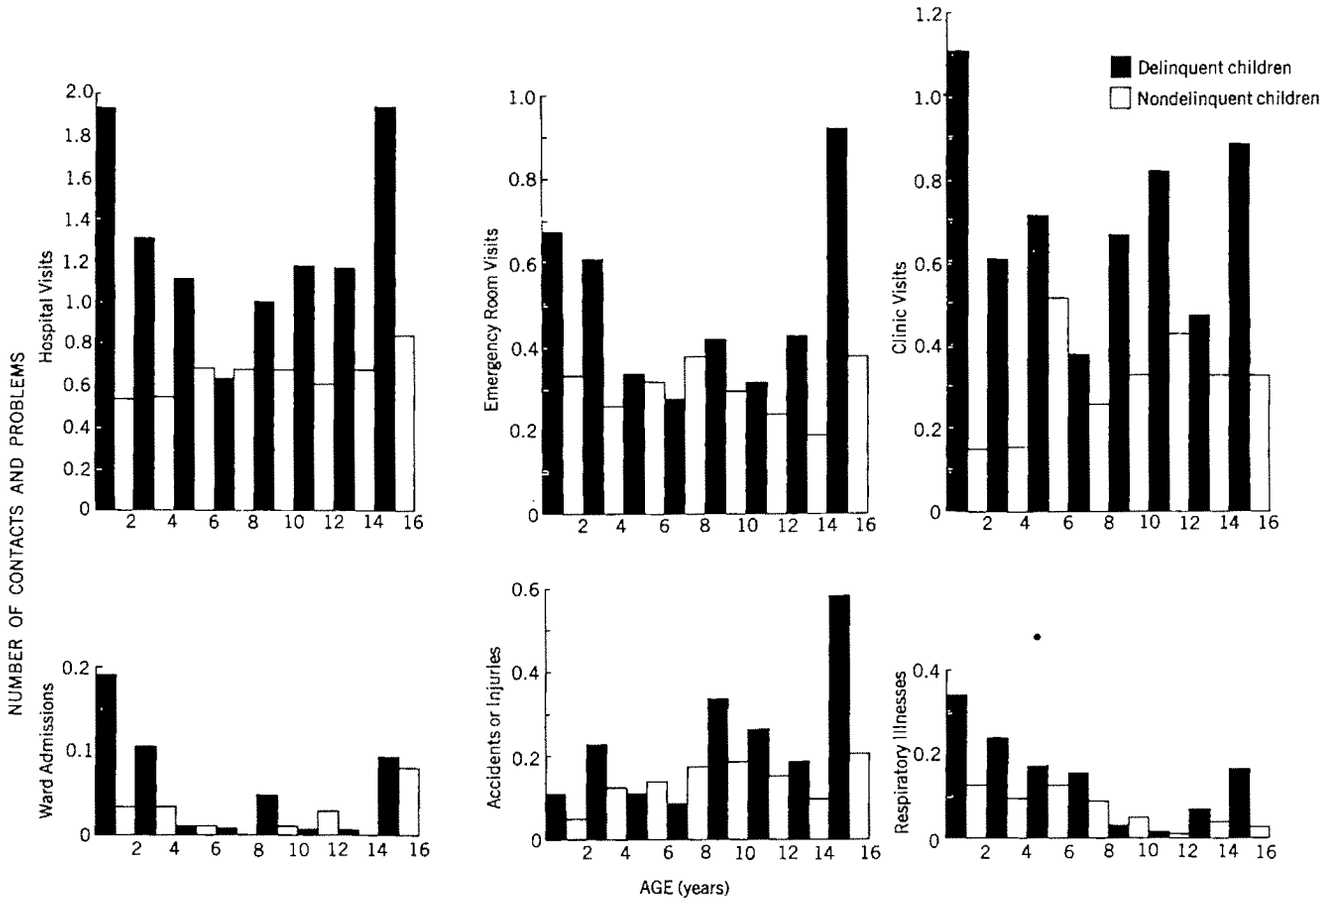
ASSESSMENT OF MEDICAL STATUS

An evaluation of the medical history of each child in the study was made on the basis of an extensive review of the child's hospital record. Our choice to limit the study to one large general hospital raises the issue of case loss. Although it would have been desirable to interview parents and children regarding medical histories, such personal contact was prohibited by the court. However, our own experience as well as that of other investigators (14) suggests that, although personal histories can be valuable clinically, they are notoriously unreliable regarding numbers of illnesses and dates of medical events, information essential to this study.

Data from other public and private medical facilities were unavailable because of issues of confidentiality; however, as far as we could determine, our two populations had equal access to other community resources, making it unlikely that one group made greater use of such clinics than the other. Furthermore, serious accidents and illnesses would have most likely been referred to the hospital. The choice of private medical care was relatively rare in both groups be-

FIGURE 1
Cumulative Hospital Contacts and Medical Problems of Delinquent and Nondelinquent Children Throughout Childhood

cause of financial considerations. At the time of study, the hospital selected tended to be used by the less affluent in the community as a source of primary care. In fact, the hospital subsequently developed a primary care center to meet the needs of the many patients who used the emergency room and clinics in this way. Finally, case loss would create underestimates of the actual prevalence of disorders and use of medical facilities in both groups.



Medical records were assessed in terms of numbers of visits to the hospital, timing of visits, use made of different hospital services (e.g., emergency room, clinics, and wards), and reasons for visits (e.g., accidents, head or face trauma, respiratory illnesses, child abuse, and psychiatric problems).

FINDINGS

The use of hospital facilities, the kinds of disorders treated, and the longitudinal picture of medical contacts are shown in tables 1 and 2 and in figures 1 and 2. As shown in table 1, delinquent children made significantly greater use of all hospital facilities than did their nondelinquent counterparts. Table 2 indicates that although delinquent children were far more likely than nondelinquent children to be seen for accidents (particularly head or face trauma) and to demonstrate psychiatric disturbance, they were no more likely than nondelinquent children to have suffered from perinatal difficulties. The timing of hospital contacts was of particular interest. As shown in figure 1 and table 3, delinquent children made significantly more hospital visits than did nondelinquent children. Differences between the two groups were most striking before age 4 and between ages 14 and 16.

When the above data were further analyzed in terms of medical events occurring within two-year intervals (see figure 2 and table 4), the years 0–2, 2–4, and 14–16 were the age intervals in which delinquent children differed most significantly from their nondelinquent peers in terms of overall hospital use. Figure 2 shows clearly the increased hospital use by delinquent children in early childhood and in adolescence in contrast to the nondelinquent group, which had relatively constant use that seemed unaffected by age.

FIGURE 2
Two-Year Interval Data on Hospital Contacts and Medical Problems of Delinquent and Nondelinquent Children

DISCUSSION

The results of this study suggest that delinquent children have significantly more hospital contacts and significantly more accidents and injuries throughout childhood than do nondelinquent children. However, to our surprise we found that delinquent children were no more likely to have experienced perinatal trauma. It was subsequent medical events that clearly distinguished one group from the other. It would seem, therefore, that medical problems throughout childhood rather than perinatal problems are associated with juvenile delinquency.

The particular clustering of medical problems during the early years (0–2 and 2–4 years) and at the onset of adolescence (14–16 years) suggests that a particular developmental factor may be operating. Both periods have in common increased physical (motor) capacities and an imbalance between inner behavioral controls and heightened impulses. In normal families the parents of very young children usually provide appropriate external controls, protecting and supporting the child until the child develops his/her own internal controls. If the parents, for any reason, are unable to provide this structure, there is a greater likelihood that immature impulsive behavior will result in frequent accidents and injuries. The parents of delinquent children are often unable to provide adequate support and protection because of their own psychopathology and the adverse social situation in which they live. The evidence for psychopathology in parents of delinquent children has been documented (7, 15, 16) and is made evident in this study by the high prevalence of child abuse in the delinquent sample.

Early accidents and injuries, possibly a consequence of parental inadequacies, may contribute to CNS dysfunction, which, in turn, further aggravates the child's difficulties with impulse control and social adaptation. The disappearance of striking differences in hospital contacts between the ages of 4 and 14 may be partially accounted for by the development of better internal controls during this period and the support offered by a school setting. Between the ages of 5 and 14 most children are in a school setting that offers protection and structure several hours each day.

With the onset of adolescence the school becomes a less effective force. Many adolescent delinquent children who have been held back over the years attend school only sporadically or drop out entirely. The burden of guidance, control, support, and protection once more falls on the shoulders of the parents. Unfortunately, the continuing inadequacy of the parents again

renders them ineffective when left to cope with their adolescent children. At the same time the adolescent's heightened impulses and increased physical strength, along with access to weapons, cars, alcohol, and drugs, make his/her impulsive behaviors most injurious to himself/herself and to others. This may partially account for the increased use of the hospital between the ages of 14 and 16 compared with the earlier years.

These findings have certain implications for the prevention of serious delinquency. A history of frequent hospital contacts for a variety of different reasons and in the absence of a single medical disorder (e.g., asthma) should alert the physician to the possibility of associated delinquent behavior and severe intrafamilial disturbance. Rather than treat each hospital contact as an isolated medical event, a frequent practice in busy emergency rooms and clinics, physicians should recognize the pattern of repeated hospital contacts for many different kinds of disorders as a possible concomitant of delinquency and as an indication for a thorough medicopsychosocial evaluation in the interest of preventing or at least curtailing maladaptive antisocial behavior.

Coexisting Childhood Schizophrenia and Myasthenia Gravis Treated Successfully with Neostigmine Bromide

BY ROBERT C. SCHNACKENBERG, M.D., AND GEORGE HOLMES, PH.D.

A 12-year-old boy who had suffered from severe schizophrenia for 8 years developed myasthenia gravis. Both disorders were treated simultaneously and successfully with neostigmine bromide. The authors suggest that these two disorders may in some cases be part of the same disease process and urge that physicians consider this possibility in patients with severe emotional problems and muscle weakness.

BIOLOGICAL factors have long been felt to contribute to the etiology of childhood schizophrenia (1–3). A child who had suffered from the symptoms of childhood schizophrenia for eight years and then developed myasthenia gravis improved dramatically after he was placed on a regimen of 15 mg of neostigmine bromide, administered orally four times a day.

Heath and Guerrero-Figueroa (4) found that the introduction of acetylcholine into the septal region of psychotic patients resulted in pleasurable feelings and alertness. However, when certain anticholinergic agents, especially atropine, were introduced into the septal region, they induced focal spiking or slow waves or both at this site. The EEGs resembled those of psychotic patients and rhesus monkeys that have received injections of taraxein fractions.

Currently, the basic abnormality in myasthenia gravis is thought to be a reduction of acetylcholine receptors at neuromuscular junctions (5). This reduction is thought to result from an autoimmune attack directed against receptors (6). Extracts of thymic tissue have been shown to contain acetylcholine receptors (7) similar to those in skeletal muscle (8). This suggests that an autoimmune reaction against acetylcholine receptors might be initiated within the thymus gland itself.

Apparently, faulty acetylcholine metabolism is involved in both of these disorders. This raises the interesting question as to the possible relationship between childhood schizophrenia and myasthenia gravis and

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

whether neostigmine bromide should be tried with other children who suffer from this disorder and have been refractory to other forms of treatment.

The odds against childhood schizophrenia and myasthenia gravis occurring in a 12-year-old boy are approximately two-hundred million to one. The concurrence may be greater. Several symptoms of these disorders overlap. When concurrence occurs, psychiatrists may diagnose the disorder as childhood schizophrenia and pediatricians as juvenile myasthenia gravis.

In the case reported in this paper, informed consent was obtained from the patient, his guardian, and both parents.

CASE REPORT

A 12-year-old boy was admitted to a residential treatment center for emotionally disturbed children in September 1969. His referring psychiatrist stated that he was "involved in a dream world and detached from reality." He did not relate to peers, had many compulsive rituals, talked to himself, had an imaginary playmate, made inappropriate facial patterns, had screaming temper tantrums when he did not get his way, had difficulty in expressing himself verbally, and needed to touch people when he talked to them. He was generally withdrawn, deficient in eye-to-eye contact, and spoke in a low tone of voice.

The patient's birth weight was 3.5 kg following a normal gestation period. However, respiratory difficulty was encountered after birth and required caffeine treatment. He was in an oxygen tent for his first 24 hours. Early development was delayed; the patient began saying simple words at age 3 and sentences at 6½. His first steps were at age 2, but he could not walk well until he was 5 years old. In contrast to these developmental delays, he could count to 10 when he was 4 years old. At age 4, he was evaluated by mental health and speech and hearing professionals, who felt he had both aphasia and childhood schizophrenia.

His parents, who had divorced in 1968, have both had multiple psychiatric hospitalizations. His mother, who is 40, has been given the diagnosis of schizophrenic reaction, simple type, and his father, schizophrenic reaction, paranoid type. Both parents were hospitalized for the first time when the patient was aged 4–6. The father was discharged from the Air Force with a 100% psychiatric disability after hospitalizations in 1962, 1963, and 1964. Both parents were cared for by their own parents, although intellectually they appear to be at least average.

The patient is the second of four siblings. An older brother died in an automobile accident in 1966, a younger brother was living in a home for orphans, and his sister was living with his mother and maternal grandmother.

In 1965 the mental health agency considered trying to move the patient and his brother away from the parents' pathological influence. In 1968 his younger brother was placed in the home for orphans because of the pathological family environment, but the patient was felt to be "almost hopeless and in extreme need of residential treatment."

Psychological testing from 1963–1967 revealed an IQ fluctuating between 82 and 91 (based on the Stanford-Binet Intelligence Scale and the Wechsler Intelligence Scale for Children [WISC]).

In his first month of residential treatment, he compulsively loved to keep score for the other boys and would not participate in their activities. His school performance was commensurate with his age, but his approach to learning was idiosyncratic and he would not take instruction from the special education teacher.

His therapeutic program consisted of special education; individual and group psychotherapy; 2 grains of thyroid extract per day for his chronic hypothyroidism (serum cholesterol and T_3 and T_4 determinations have been normal); and specific work on his sense of body image, motor coordination, and time and spatial concepts. In March 1970 an inappropriate posturing of his left arm was noted, and he explained that "bad things would happen if he moved his left arm normally." In June 1970 a progress note stated that he had made "minute progress." He was noted to be more assertive and less fearful of his peers and performed better in the group situations, with less withdrawal to sleep during activities. At school he still displayed a rigid approach to learning and was poor in oral and written language expression and abstract thinking. His mother and maternal grandmother, who had been worked with throughout the year, seemed to be less overprotective than in the past.

After the July vacation month the patient returned to the residential treatment center in August 1970 with some shifting of symptoms. His posture was more slumped, with his chin resting on his chest. His speech was slurred and barely audible, and he complained of difficulty in swallowing solid foods. In October he was noted to tire easily, and his extraocular muscles also became affected. At this time the diagnosis of myasthenia gravis was made, and he was placed on 15 mg of neostigmine bromide four times a day. His posture normalized, his speech became more articulate, he became more alert, eye muscle function normalized, and swallowing improved. However, the most noteworthy improvement was his increased ability to communicate and relate to people, his new-found assertiveness, and the subjective feeling of several people who examined him that he had become more emotionally related to other people. (Neostigmine ordinarily penetrates the blood-brain barrier poorly [9]. However, the usual penetration of 15% may be sufficient or may increase under pathophysiological conditions.)

The patient continued to make excellent progress, and he was discharged from the residential treatment center in 1972. He has resided in a children's home since that time because his parents are too emotionally

ill to care for him. He has shown no signs of schizophrenia since 1970 and would best be described as an overly perfectionistic or obsessive-compulsive personality, a frequent residual of recovered childhood schizophrenia as noted by Bender (10, p. 215).

Psychological assessment preceding the patient's successful treatment with neostigmine bromide revealed a

> 12-year-old male who behaviorally and from psychological testing manifests both organic and emotional problems. The organic manifestations are in the area of generalized restlessness, poor concentration-attention ability and perseveration. Emotional features, probably developed as a means of compensating for the organic problems, are compulsive rituals, anxieties, and at times lability and expansiveness of his affect.

The most recent intellectual assessment, in 1973, revealed a full-scale IQ of 96 (based on the WISC).

The patient has been followed at monthly outpatient intervals since 1972. During the 1972–1973 school year he was voted the "best-liked boy in his class" and obtained a B average. He was able to compete in sports with other boys his age, with his major difficulty being some residual social awkwardness. In April 1974 it was decided after neurological consultation to withdraw him from the neostigmine bromide; he was placed in the hospital where this was accomplished without difficulty. He continued to be followed at monthly intervals with no recurrence of childhood schizophrenia and myasthenia gravis. His only medication was 2 grains of thyroid extract per day. (It should be noted that hypothyroidism frequently accompanies myasthenia gravis.)

We offer the following speculations as to why the symptoms did not recur with the removal of neostigmine.

1. Both disorders occasionally remit spontaneously during adolescence (11, p. 668; 12).
2. The predisposition to allergic reactivity changes as a function of age (13, p. 13).

DISCUSSION

Strauss and associates (14), using fluorescent antibody techniques, demonstrated the presence of globulin on the A-band striations of affected muscles of patients with myasthenia gravis. Lindstrom and associates (6), Aharonov and associates (7), and Kao and Drachman (8) have shown that skeletal muscle cells in the thymus may initiate an autoimmune attack, reducing available acetylcholine receptors at neuromuscular junctions.

The studies of myasthenia gravis by Strauss and associates (14) led Heath and Krupp (15) to their immunological hypothesis of schizophrenia. Heath and associates (15,16) postulated that taraxein might represent an antibody capable of binding itself to specific antigen sites in septal tissues of the brain to cause an anticholinergic effect similar to that on the muscles of patients with myasthenia gravis. Heath and Guerrero-Figueroa (4) noted a schizophrenic-like psychosis caused by impairment of acetylcholine activity in the septal region. In addition, Heath and Krupp (15) found that control sera from a patient with myasthenia gravis induced psychosis in a monkey.

Inherited factors may be significant, since Pirskanen (17) found a genetic association between myasthenia gravis and the human leukocyte antigen system. HLA-8, coded on autosome number 6, is associated with neurovegetative lability as well as autoimmune and endocrine disorders (17).

This supports the hypothesis that a subgroup of schizophrenia may be a central autoimmune disorder, which in some cases may be related to myasthenia gravis, a peripheral autoimmune disorder.

Pituitary Thyrotropin Response to Thyrotropin-Releasing Hormone in Affective Illness: Relationship to Spinal Fluid Amine Metabolites

BY PHILIP W. GOLD, M.D., FREDERICK K. GOODWIN, M.D., THOMAS WEHR, M.D., AND ROBERT REBAR, M.D.

The authors studied pituitary thyrotropin, i.e., thyroid-stimulating hormone (TSH), response to thyrotropin-releasing hormone (TRH) in patients with primary affective disorder. There were no overall differences between either depressed or manic patients and normal controls; however, the TSH response was significantly lower in the unipolar depressed patients than in either bipolar depressed patients or normal subjects. Bipolar patients in the manic phase tended to have a lower response than bipolar depressed patients. In the unipolar group, the TSH response showed a significant negative correlation with the serotonin metabolite 5-hydroxyindoleacetic acid (5-HIAA) in the CSF. These neuroendocrine responses may constitute markers of specific monoamine dysfunction in subgroups of patients with affective illness.

SEVERAL ASPECTS of the symptom complex of affective illness, such as disturbances in sleep, altered energy levels, changes in appetite and libido, diurnal variation in symptoms, and amenorrhea, suggest hypothalamic dysfunction. The abnormalities of neuroendocrine response seen in affective illness have been thought to be biological representations of this hypothalamic dysfunction. Interest in the hypothalamic-pituitary axis has been further stimulated by recent findings that the monoamine neurotransmitters thought to play an important role in the pathogenesis of affective illness modulate the synthesis and release of a number of hypothalamic peptides and pituitary hormones (1). Thus, examination of pituitary hormones in plasma can shed light on the functional activity of biogenic amine systems. Moreover, these peptides and hormones may have behavioral effects or influence the metabolism of biogenic amines or other central nervous system regulators (2). The recognition of this crucial relationship between central nervous system function and neuroendocrine secretory systems provides the basis for new methods for investigating the biological basis of affective illness.

Dr. Rebar was Clinical Associate, National Institute of Child Health and Human Development, Bethesda, Md.; he is now Assistant Professor of Reproductive Medicine, University of California School of Medicine, San Diego, La Jolla, Calif.

METHOD

Our subjects were 23 patients with primary affective disorder, diagnosed independently by two psychiatrists according to the criteria of Spitzer and associates (3), and 10 normal volunteers, all hospitalized on clinical research units at the National Institutes of Health. The depressed patients were subdivided into unipolar and bipolar groups based on the absence or presence, respectively, of a history of mania and/or hypomania (3). All patients adhered to a controlled monoamine diet and received no medications for 3 weeks before the study. After an overnight fast, a 19-gauge scalp vein was inserted into an antecubital vein and kept open with a slow drip of normal saline. Baseline thyroid-stimulating hormone (TSH) levels were determined 15 minutes before and just before the infusion of 500 μg of synthetic thyrotropin-releasing hormone (TRH), given as an I.V. bolus over 30 seconds. Following the TRH infusion, blood was drawn every 15 minutes for at least 1 hour and analyzed for TSH. The TSH response to TRH represented the difference between the maximum TSH increment following TRH infusion and the average of the baseline TSH values. TRH was assayed by the double antibody technique. The intra- and interassay coefficients of variation were 6.0% and 14.0%, respectively. The limit of assay sensitivity was 2.0 μU/ml.

The major metabolites of serotonin, norepinephrine, and dopamine in the central nervous system (5-hydroxyindoleacetic acid [5-HIAA], 3-methoxy-4-hydroxyphenyl glycol, and homovanillic acid [HVA], respectively) were analyzed in cerebrospinal fluid (CSF) after 18 hours' pretreatment with probenecid (100 mg/kg), a drug that blocks the egress of both 5-HIAA and HVA out of the central nervous system, resulting in their accumulation in the CSF. CSF was collected, stored, and analyzed as previously described (4). The lumbar punctures and the TRH infusions were performed on separate days but under similar drug-free conditions and during the same clinical state, i.e.

mania or depression. When some of the patients were given lithium and then retested, the lithium level was maintained between 0.8 and 1.2 mEq/liter. Cycling premenopausal women were tested only during the low estrogen, early follicular phase of the cycle (5).

RESULTS

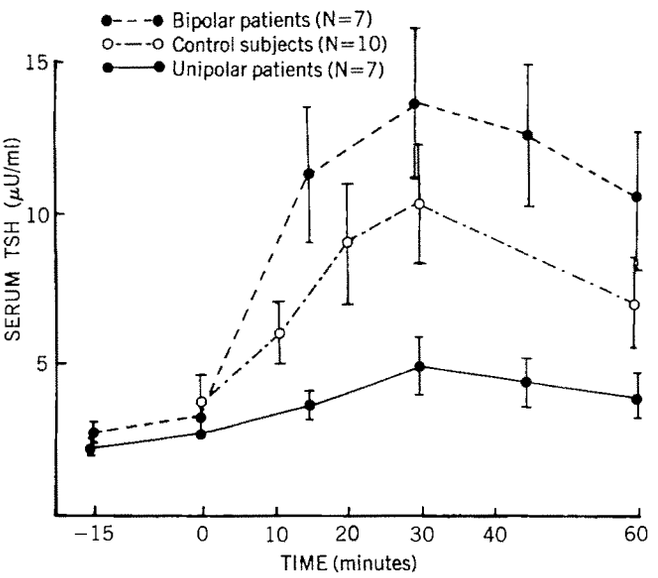
There was no significant difference in baseline plasma T_3, T_4, or TSH between any of the subgroups tested. When the TSH response to TRH was examined, no relationship was found to age, sex, baseline plasma T_3, T_4, or TSH, either in the overall groups of patients or within any subgroup.

No significant difference was noted when the TSH response in the overall group of depressed patients was compared with the TSH response in control subjects. However, the unipolar patients showed a significantly lower TSH response compared with bipolar patients ($p<.01$) and controls ($p<.01$) (see figure 1). The 9 bipolar patients in the manic phase tended to have a lower response than the 7 in the depressed phase (8.82 ± 1.44 μU/ml versus 12.31 ± 2.21 μU/ml; $p<.10$, Student's t test). Chronic lithium treatment significantly increased the TSH response ($p<.01$, paired t test); this change was accompanied by a significant decrease in T_4 ($p<.05$, paired t test).

As illustrated in figure 2, a significant negative correlation was found in the 6 unipolar depressed patients on whom lumbar punctures had been performed between the probenecid-induced accumulation of 5-HIAA in the CSF and the TSH response ($r=.89$, $p<.05$). There were no other significant correlations between amine metabolites in CSF and the TSH response, either overall or in the various subgroups tested.

Two unipolar patients with blunted TSH responses in depression were studied in the drug-free state following recovery; in each the TSH response returned to normal. In one of these patients, CSF 5-HIAA was also obtained during depression and following recovery; in the recovered state, the 5-HIAA fell approximately 50% in apparent association with the normalization of the TSH response.

FIGURE 1
TSH Response to TRH in Depressed Patients and Controls



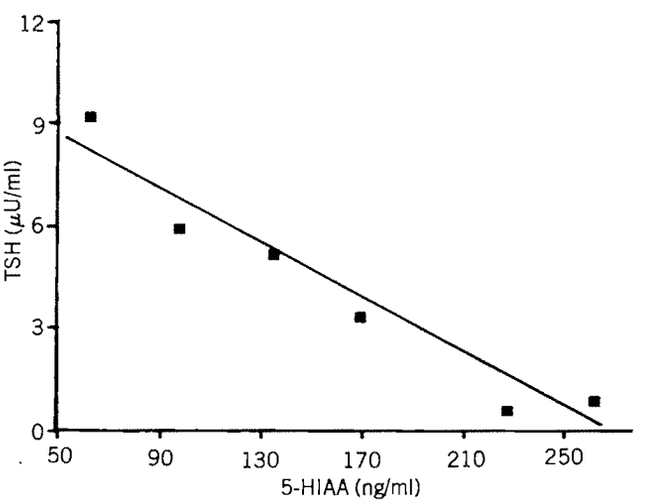


FIGURE 2
Correlation Between Age, Corrected CSF 5-HIAA, and Difference in TSH Values in 6 Unipolar Patients*

*r=.89; p<.05.

DISCUSSION

Factors that might be associated with a blunted TSH response include increased T_3 and T_4 (6), drugs such as aspirin (7), prolonged fasting (8), and elevated glucocorticoids (9). On the other hand, elevated TSH response can be associated with decreases in T_3 or T_4 (10) and elevated estrogen of either endogenous or exogenous origin (4); thus, studies in normal subjects indicate that the TSH response is slightly higher in women than in men and is somewhat higher in women during the midmenstrual cycle compared with the early follicular phase (4). In addition, alterations in the sleep-wake cycle or in the level of endogenous TRH could also affect the TSH response.

A number of these factors can be excluded from influencing the findings reported here. Patients received no drugs during the study, and menstruating women were tested only during the low estrogen phase of the cycle. Since there are more women in the unipolar group than in the bipolar group, unequal sex distribution cannot account for the lower responses in the unipolar patients.

The sleep disturbances seen in manic and depressed patients could also affect the TSH response, since TSH levels tend to be high during waking hours and to fall rapidly after the onset of sleep (11). However,

there was no relationship between TSH response and hours of sleep. Evaluation of the role of endogenous TRH levels on the TSH response awaits a clinically applicable TRH assay.

Glucocorticoids have been reported to be elevated in unipolar depressed patients (12), a factor that could account for the lower TSH responses in this group. However, it has also been recently reported that there is no significant difference in glucocorticoid levels between unipolar and bipolar depressed patients (12, 13), so elevated glucocorticoids may not be the governing factor in the lower TSH response of unipolar depressed patients. Alternatively, elevated glucocorticoids and the lower TSH response could each be markers for an underlying abnormality in neurotransmitter function in unipolar depressed patients.

Because the TSH response can be considerably magnified by even small, nonsignificant decrements in T_3 and T_4 (10), the fact that there were no significant differences in the level of circulating thyroid hormones among the various groups of subjects does not exclude thyroid hormone levels as a factor in this study. Thus, the antithyroid effects of lithium, which might persist for several weeks after discontinuation of the drug, could result in a greater TSH response in patients who had received previous lithium therapy during the course of their illness. Although none of the subjects received any drugs for at least 3 weeks prior to study, 5 of 7 bipolar and only 1 of 7 unipolar patients had received lithium therapy earlier in the course of their illness, a factor that could contribute to the difference in TSH response between these groups. The possible contribution of previous lithium therapy to TRH studies in affective illness requires further evaluation.

Although some bipolar patients have been included in previous reports of blunted TSH responses in depression (14–19), the question of differences in the mean response between unipolar and bipolar groups was not addressed. The factor of previous lithium therapy may play a role in our results; however, the unipolar-bipolar difference noted here is also consistent with a variety of clinical, genetic, pharmacological, and biological data (20) which suggest that these subgroups may represent different illnesses.

It is generally accepted that the hypothalamic-pituitary-thyroid (HPT) axis is regulated by TRH, which is produced within the central nervous system in the area of the hypothalamus. The cells that synthesize and release TRH possess the ability to respond to activation and inactivation by monoaminergic neurotransmitters (1). The TSH response to TRH is also modulated by alterations in the functional activity of monoaminergic neurotransmitter systems, presumably at the level of the pituitary (1). Thus, it is at the level of both the hypothalamus and the pituitary that monoaminergic neurotransmitters regulate HPT function and affect the TSH response to TRH. Although it has been assumed that CSF 5-HIAA primarily originates in neurons with a paraventricular origin, the TSH to CSF 5-HIAA correlation suggests that CSF 5-HIAA might reflect the activity of serotonergic systems in the hypothalamus or pituitary; recent anatomic studies suggest substantial interconnectedness between the hypothalamic-pituitary axis and paraventricular and other brain regions via axonal and portal transport systems and the CSF communication pathway (21).

The monoaminergic control of the synthesis and release of TRH itself is unclear. It is known, however, that in experimental animals (22, 23) and in man (24–26), both dopaminergic and serotonergic stimulation inhibit the TSH release and response to a variety of stimuli. Thus, the blunted TSH response in unipolar depressed patients may be associated with increased serotonergic or dopaminergic activity, perhaps particularly the former, in light of the significant negative correlation between the TSH response and CSF 5-HIAA. Viewed in this way, the TSH response data would be consistent with a hypothesis of increased functional serotonergic activity in unipolar depression. The previously reported effect of lithium treatment on TSH response (27) was confirmed in this study. Although it has been assumed that this effect is secondary to the antithyroid effect of lithium, an additional factor might involve direct effects of lithium on the serotonergic system (28).

Other neuroendocrine work from this laboratory is also compatible with a hypothesis of increased serotonergic activity in some severely depressed unipolar patients. We recently reported that the 24-hour urinary free cortisol production was significantly elevated in a group of unipolar depressed patients compared with control subjects (13) and that the degree of elevation correlated positively with the CSF 5-HIAA. This finding is in agreement with data from both experimental animals and man, indicating that serotonin may be a neurotransmitter that drives the hypothalamic-pituitary-adrenal axis (29, 30). Elevated glucocorticoids and a blunted TSH response may thus each reflect increased functional serotonergic activity in some unipolar depressed patients.

The tendency for a greater TSH response in bipolar depressed patients compared with bipolar patients in the manic phase is also of interest and could reflect alterations in the functional activity of dopaminergic systems in bipolar depressed patients. We have recently reformulated a "dopamine hypothesis of affective illness," integrating these neuroendocrine data with relevant metabolite and pharmacological response findings (31).

The concept of biochemical heterogeneity in the affective disorders has recently been given support by reports of apparently bimodal distributions of amine metabolites (32, 33) and by evidence that separable amine metabolite subgroups may show differential responses to different antidepressant drugs (33). Work is now under way to determine if TSH response and other neuroendocrine measures may also be useful in further delineating the question of biochemical heterogeneity and its relationship to diagnostic subgroups and pharmacological response.

Tardive Dyskinesia in Young Adults

BY DANIEL TARSY, M.D., ROBERT GRANACHER, M.D., AND MICHAEL BRALOWER, M.D.

The authors describe two cases of tardive dyskinesia in which severe axial dystonia and intense facial grimacing produced marked discomfort as well as social and physical disability. Both patients experienced the onset of psychiatric symptoms as young adults, showed a prompt response to antipsychotic drug therapy, and were subsequently left on maintenance treatment for indefinite periods. The severity of this frequently irreversible and disabling condition warrants careful consideration in the use of long-term antipsychotic drug treatment in the young psychiatric outpatient population.

IT IS well known that the chronic use of antipsychotic drugs may lead to the appearance of a persistent, involuntary movement disorder known as tardive dyskinesia (1, 2). This syndrome has been reported in patients exposed to virtually all phenothiazines and occasionally a thioxanthene (3) or butyrophenone (4). Although many cases occur in institutionalized patients with chronic psychiatric disorders, the syndrome also appears in psychiatric outpatients and nonpsychotic patients treated with phenothiazines for psychoneurosis, chronic gastrointestinal disturbances, chronic pain, and personality disorders (5). Although a relationship with organic brain disease was emphasized in early reports, subsequent studies have demonstrated no significant association with previous brain damage, ECT, or frontal leukotomy (2). Although there appears to be an increased risk for tardive dyskinesia in patients older than age 50 (6), the condition is by no means restricted to the elderly; it occurs in middle-aged and young adults as well. The purpose of this communication is to report the appearance of a remarkably severe and disabling form of tardive dyskinesia in two young men and to thereby emphasize the risks inherent in the long-term treatment of young individuals with antipsychotic drugs.

Dr. Tarsy is Staff Neurologist, Boston Veterans Administration Hospital, 150 South Huntington Ave., Boston, Mass. 02130. He is also Assistant Professor of Neurology, Boston University School of Medicine, and Lecturer in Neurology, Harvard Medical School, Boston, Mass. At the time this work was done Dr. Granacher was Clinical and Research Fellow in Psychopharmacology, Psychiatric Research Laboratories, Massachusetts General Hospital, and Clinical Fellow in Psychiatry, Harvard Medical School, Boston, Mass. He is now Assistant Professor, Department of Psychiatry, University of Kentucky College of Medicine, and Chief, Intensive Treatment Service, Eastern State Hospital, Lexington, Ky. At the time this work was done Dr. Bralower was a resident in neurology, Boston Veterans Administration Hospital, and Senior Chief Resident in Neurology and Teaching Fellow, Department of Neurology, Boston University School of Medicine. He is now in the private practice of neurology with New England Neurological Associates, P.C., Lowell, Mass.

CASE REPORTS

Case 1. A 23-year-old enlisted man was admitted to a military hospital in August 1972 for depression, delusions, flight of ideas, and inappropriate affect. There was no family history of neurological or psychiatric disorder. Neurological examination, laboratory studies, skull X rays, brain scan, and EEG were normal. A diagnosis of acute undifferentiated schizophrenia was made, and he was treated with 20–30 mg of trifluoperazine daily, with rapid improvement. Within 2 months he was free of evident thought disorder and was discharged from military service. He was followed in a Veterans Administration hospital psychiatric outpatient facility where he remained free of psychiatric symptoms and was maintained on 30 mg of trifluoperazine daily. In October 1973, 300 mg of thioridazine daily was substituted for the trifluoperazine. In March 1974 it was noted for the first time that the patient had choreoathetosis and dystonia involving the left arm, shoulder, and mouth. Thioridazine was discontinued and 8 mg of trihexyphenidyl daily was administered. The dyskinesias worsened and became associated with marked motor restlessness, diaphoresis, excessive thirst, and a 40-pound weight loss. Trihexyphenidyl was discontinued and the patient was referred to the neurology service of the Boston VA Hospital in May 1974.

The findings from a general examination were normal except for diaphoresis and a pulse rate of 120–140 during periods of physical hyperactivity. There was generalized motor restlessness; continuous facial grimacing; intermittent blepharospasm; spasmodic contractions of the tongue, jaw, and facial muscles; torticollis and retrocollis; athetotic movements of the hands; and abnormal posturing of the arms in abduction and extension (more severe on the left than the right side). The patient frequently assumed bizarre positions in order to abort the dyskinesias, such as crouching in bed on all fours with the top of his head pushed against a pillow or standing with his forehead pressed forcibly against a wall. The other findings from the neurological examination were normal. Findings from routine laboratory studies, serum copper and ceruloplasmin, urinary copper, serological studies, calcium, and thyroid function studies were normal. Slit-lamp examination showed no Kayser-Fleischer rings. Skull X rays, EEG, brain scan, and cerebrospinal fluid were normal. A psychiatric consultant found no evidence of active thought or affective disorder.

Eight mg of haloperidol daily produced prompt and complete abolition of all dyskinesias except for mild posturing of the left arm while the patient was walking. Because of concern over the long-term effect of continued exposure to anti-

psychotic drugs, haloperidol was discontinued after several weeks, with a prompt recurrence of all dyskinesias. Intravenous diphenhydramine, benztropine, and physostigmine and oral diphenhydramine, dantrolene, propanolol, and deanol had no effect. Severe depression ensued, and a regimen of 8 mg of haloperidol daily was resumed, with a virtual disappearance of all dyskinesias within several days. During the next 3 months the patient exhibited only mild posturing of the left arm and pursing movements of the lips. However, mild drug-induced parkinsonism appeared for the first time, and the patient became increasingly depressed and paranoid. In February 1975 the patient committed suicide. There was no postmortem examination.

Case 2. A 19-year-old musician began exhibiting severe obsessive-compulsive, ritualistic behavior requiring psychiatric hospitalization in 1966. An underlying schizophrenic process was suspected, and the patient was treated with 20–40 mg of trifluoperazine daily, with resolution of symptoms within 4 weeks. He continued this medication and led a normally active professional and social life until May 1974. At that time he reported that involuntary eye blinking had been present for 2 years and arching of the torso and restless movements of the arms and legs for 2 months. While sitting in his car he would repeatedly arch his torso and forcibly press the back of his head into the seat. Trifluoperazine was discontinued, and he was referred to the psychiatric outpatient department of Massachusetts General Hospital. Examination disclosed continuous, large amplitude dystonic movements and postures of the neck and torso. His gait was characterized by an exaggerated lordotic posture of the torso and forward thrusting movements of the abdomen and hips. There was frequent eye blinking, blepharospasm, choreoathetotic hand movements, vermicular tongue movements, and repeated stereotyped caressing movements of his hands to his face and moustache. He denied any subjective compulsion to perform the movements. The other findings from the neurological examination were normal.

Family history included schizophrenia in one sister and obsessive behavior in the mother; there was no family history of neurological disorder. Findings from routine laboratory studies, serum copper and ceruloplasmin, thyroid function studies, calcium, skull X rays, EEG, brain scan, liver scan, and slit-lamp examination were normal.

Treatment with trihexyphenidyl, diphenhydramine, diazepam, 2 mg of haloperidol daily, and 4 g of L-dopa daily had no significant effect. Three grams of deanol daily appeared to reduce the involuntary movements, but because of a marked increase in obsessive symptoms deanol was discontinued; there was no significant increase in dyskinesia. When the patient was hospitalized in February 1975 he displayed obsessive-compulsive signs and symptoms, auditory hallucinations, paranoid delusions, a thought disorder, and the persistent dyskinesia. A regimen of 60 mg of haloperidol daily was begun, with improvement in the patient's psychiatric symptoms and a significant reduction in the dyskinesia. He is currently followed as an outpatient; both the dyskinesia and psychiatric symptoms persist.

DISCUSSION

These two individuals display a number of features in common. Both manifested the onset of psychiatric symptoms as young adults, showed a prompt and satisfactory response to trifluoperazine, were left on maintenance treatment, and subsequently enjoyed an interval free of psychiatric symptoms. The subsequent insidious appearance of involuntary movements during treatment with phenothiazines, exacerbation of dyskinesia following drug withdrawal, and subsequent suppression with haloperidol are all quite typical of tardive dyskinesia (2). Insofar as possible, other neurological disorders have been excluded. The motor behavior of both individuals was dominated by large amplitude, bizarre, often grotesque dystonic postures of the torso and extremities. These postures were extremely uncomfortable, caused intense embarrassment, and virtually precluded satisfactory social relationships and useful employment.

Tardive dyskinesia is virtually unique in the remarkable variety of hyperkinetic involuntary movements that may appear, including orofacial dyskinesia, facial tics, grimacing, chorea, athetosis, dystonia, torticollis, and motor restlessness (2). Although orofacial dyskinesia is probably the best known feature of the syndrome and often appears first in older patients, involuntary movements of the extremities and torso are usually apparent as well.

In younger individuals involvement of the extremities and torso is often more prominent and may include unusual postures of hyperextension and abduction of the arms, ballistic movements, exaggerated and lordotic postures of the trunk, shoulder shrugging, and rotatory pelvic movements. A number of studies (7–10) have reported several striking examples of tardive dyskinesia in patients below age 50, with marked axial involvement including retrocollis and opisthotonic arching of the back; some of the cases strongly resembled our own. A syndrome resembling tardive dyskinesia has also been reported in children following the withdrawal of antipsychotic drugs; the involuntary movements primarily involve the extremities, torso, and, only rarely, the mouth (11). The effect of age on the topographic distribution of tardive dyskinesia therefore bears some resemblance to phenothiazine-induced acute dystonic reactions and idiopathic torsion dystonia (dystonia musculorum deformans), in which children and adolescents tend to suffer generalized axial involvement while adults often manifest more localized face and neck involvement (12, 13).

It is sometimes stated that patients with tardive dyskinesia are relatively unaware of and undisturbed by their movements. In our experience, however, this is more characteristic of patients with coexisting chronic psychosis or dementia. As we have emphasized in this report, young individuals, who often manifest generalized dyskinesias, suffer obvious discomfort, embarrassment, and social and physical disability as a result of the disorder.

The management and treatment of tardive dyskinesia remain particularly difficult problems and have been reviewed in detail elsewhere (2). Prevention must be considered of paramount importance. The use of long-term antipsychotic drug therapy in the treat-

ment of conditions responsive to other modes of therapy should be discouraged. In addition, the decision to maintain patients on long-term drug therapy following a single acute schizophrenic reaction must be weighed with particular care. Patients should be examined at regular intervals for early features of dyskinesia such as vermicular tongue movements, facial tics, particularly frequent eye blinking, and subtle athetotic finger movements. Drug "holidays" have also been recommended in order to reduce drug exposure, unmask latent dyskinesia, and assess the need for continued medication (1, 2). Unfortunately, the patients described in this report are not unique and, in fact, are only two of several young individuals with extensive and disabling tardive dyskinesia whom we have seen in recent years. We have presented detailed descriptions of their disorder with the aim of reemphasizing the gravity of the condition, particularly when it appears in the young psychiatric outpatient population.

CLINICAL AND RESEARCH REPORTS

This section contains reports of new clinical or laboratory observations, single cases of unusual interest or importance, descriptions of pilot studies, suggestions for future research, etc. Reports should be submitted in duplicate, typed double spaced throughout, and may contain 1,000 words, no more than 1 table, and a maximum of 10 pertinent references. Figures cannot be used. Reports will be reviewed by at least one referee and the Editor; the author will receive a postcard informing him/her of the disposition of the submission. Reports will be edited for clarity and conformance with Journal *style.*

Juvenile Manic-Depressive Illness

BY JAMES H. WHITE, M.D., AND GREG O'SHANICK, M.D.

Although manic-depressive illness is described as a disease of adulthood, Kraepelin (1) observed that 0.4% of his manic-depressive patients had evidence of sporadic mania before the age of 10. In 1960, Anthony and Scott (2) formulated the following criteria for diagnosis of childhood manic-depressive illness: 1) an abnormal psychiatric state similar to the classical description; 2) a family history of manic-depressive disorders; 3) an early tendency for cyclothymic mood with increasing severity and length of mood swings, and delirious manic or depressive outbursts occurring during febrile illness; 4) recurrent or periodic mood disorder (at least two episodes); 5) diphasic moods showing swings of pathological dimension; 6) minimal influence of environment on symptoms; 7) severe symptoms requiring inpatient treatment; 8) an extroverted personality; and 9) absence of features of schizophrenic or organic states.

Psychogenic etiologies have not been proved, and psychogenic features are less apparent after the affective disorder is controlled with lithium (3–6). Weinberg and Brumback (7) noted a positive correlation with hyperactivity in three documented cases. An X-linked genetic factor has also been proposed (8).

Case Report

The patient was a 15-year-old boy who was hospitalized in an acutely agitated state with incoherent speech.

On admission he displayed markedly grandiose delusions, flight of ideas, loose associations, and general agitation. He claimed to have taken amphetamines, barbiturates, LSD, and marijuana. He was very disoriented; he claimed that it was January 1961, that he was in "God's world," that he had nothing to worry about, and that he, in fact, was God's son. He talked to God constantly and claimed to be able to see him.

The physical and neurological examinations were normal, as were laboratory studies done at admission. Drug screens were negative. His initial EEG displayed one brief paroxysm of epileptiform activity, but a repeat tracing was normal.

The patient was an identical twin; both the other twin and the mother showed cyclothymic personalities. The father was subject to recurring psychotic depressions. Affective disorders were also present in the paternal grandfather, the paternal grandmother, and several paternal aunts who were diagnosed as schizo-affective. His early development was mildly delayed, and he was diagnosed as being hyperactive at age 6 and treated with stimulant drugs without effect. On two occasions he was hospitalized for behavior control, with no change in his extreme hyperactivity and impulsiveness. His IQ was borderline. Throughout his childhood, he was noted to have marked mood swings unrelated to environmental events. Behavior problems at home and school continued, culminating in a series of runaway episodes that led to this admission.

Phenothiazines were tried, but the patient developed erythema multiforme. Haloperidol was substituted to control the patient's agitation. Lithium carbonate was started at an initial dose of 1800 mg/day until a serum lithium level of 1.0 mEq/liter was reached. The dosage was then decreased to 1200 mg/day. A marked improvement was noted in the patient's behavior after 4 days on lithium: his psychomotor agitation decreased, delusions of grandeur disappeared,

Dr. White is Assistant Professor of Psychiatry and Pediatrics, University of Texas Medical Branch, Galveston, Tex. 77550, where Dr. O'Shanick was a senior medical student when this work was done. Dr. O'Shanick is now a resident in psychiatry, Duke University, Durham, N.C.

thought processes were more coherent, and orientation was appropriate. Supportive psychotherapy was initiated at this time.

The patient developed a second episode of erythema multiforme, which resolved when the haloperidol was stopped. Four weeks after his initial improvement with lithium treatment, he became markedly depressed and showed psychomotor retardation. The lithium was discontinued, but 1 week later manic symptoms reappeared, with gross flight of ideas, psychomotor agitation, and grandiose auditory and visual hallucinations. Lithium was started again; oral fluphenazine was added to control his agitation while his serum lithium level was increasing to therapeutic levels. He had no evidence of allergic reactions to fluphenazine. Over a period of 3–5 days, his agitation, affect, and thought processes improved. He was discharged 2 weeks later to outpatient follow-up. Two weeks after discharge, the fluphenazine was stopped without a recurrence of symptoms. The patient has reentered a special school program and lives with his mother and stepfather. He continues to take lithium carbonate, 1200 mg/day, and is seen in supportive outpatient psychotherapy. There has been no further evidence of manic or depressive symptoms.

Discussion

Previous reports of children and young adolescents eventually diagnosed as manic-depressive indicate that they were often originally misdiagnosed as hyperactive. However, these children fail to respond to stimulant drug therapy in the way the hyperactive child usually does (3, 7).

This case is presented to emphasize the fact that manic-depressive illness can be seen very early in life. It often resembles the hyperactive child syndrome initially, but closer investigation and a more thorough history reveal significant differences. As the child enters adolescence, the symptoms more closely resemble the adult form of manic-depressive illness. Early recognition is important because these patients respond to lithium but not to other treatments.

In the child or young adolescent with increased psychomotor activity, marked mood swings, and a positive family history of affective disorders, manic-depressive illness should be considered. A favorable response to lithium does not remove the need for psychotherapy to help the patient understand and cope with his illness. Psychotherapy is also necessary to help the individual deal with the interpersonal problems associated with a life-long illness.

Transcultural Attitudes Toward Antisocial Behavior: Opinions of Mental Health Professionals

BY JAMES M.A. WEISS, M.D., AND MARGARET E. PERRY, M.S.

Antisocial and criminal behaviors are complex phenomena often associated with psychiatric disorders (1). However, labeling theory, a major new direction in crime research, supports the view that deviant characteristics reflect the obverse of the norms and values of the larger community, which defines the rules by which certain behaviors come to be considered aberrant (2). There is evidence that mental health professionals may be influenced by cultural definitions of aberrant behavior (3, 4). However, these public norms, values, and attitudes are generally implicit, and little qualitative research has been done in this area.

For these reasons, we have developed a series of continuing projects concerned with public attitudes toward crime and antisocial behavior in various cultures and subcultures. In the first three studies (5–7), we found that people in urban areas scattered throughout the world are most concerned about crimes of violence (especially homicide), theft, exploitation, and public dishonesty. Other kinds of antisocial behavior apparently are seen as important crimes by only relatively small groups within the various populations studied. More people endorse a traditional, moralistic, punitive approach to social control of crime than a preventive-rehabilitative approach, although a majority wants an organized, problem-solving approach. Significant differences among respondents in perceptions of what

Dr. Weiss is Professor and Chairman, Department of Psychiatry, University of Missouri—Columbia School of Medicine, Columbia, Mo. 65201, where Ms. Perry was Visiting Assistant Professor (Mental Health Sciences) when this work was done.

constitute the most serious crimes are related primarily to geographic location, but differences in defining strategies for control are related to social class, educational, and experience variables: upper-class individuals and experts tend to endorse preventive and rehabilitative strategies. The present study will describe such variances in opinion among mental health professionals.

Method

Most studies of public opinion involve quantitative rather than qualitative approaches. However, by using Thompson's schema for the measurement of qualitative attributes (8), Stephenson (9) developed formal models for investigation in different cultural settings of public opinion regarding complex problems to determine in-depth, authentic patterns of opinion and to test the invariance of the factors.

We modified Stephenson's design to obtain a balanced sample of empirically derived representative opinions by using small-sampling techniques. This design involved a stratified quasi-balanced factorial sampling of 30–35 subjects in each of eight large cities (Athens, Bombay, Dublin, Istanbul, London, Paris, St. Louis, and Tokyo). The procedure allows us to classify responses by age, sex, socioeconomic status, and degree of expertise and/or involvement of the respondents in each city, yielding a universe of 2,603 different statements of opinion.

These statements then were subjected to content analysis and categorized into various subsets. The data were examined by an analysis of variance approximation and a centroid factor analysis. The requirement for statistically significant differences was a p value of .05 or less; p values of .50 or more were considered as indications of a high probability of agreement among the various demographic subgroups. Further details of method and category definition can be found in previous papers (6, 7, 10).

Results

Among the 258 respondents in our sample, there were 41 mental health professionals (23 psychiatrists, 7 psychologists, 6 nurses, and 5 social workers) distributed randomly throughout the eight sample cities. Approximately two-thirds of this group were in the middle age range (30–59); two-thirds were male. All of the mental health professionals (except 1 nurse in this sample) were upper class by our definition. Most psychiatrists and psychologists were categorized as "experts," while most nurses and social workers were classified as "informed."

The first noteworthy finding was the high level of agreement among the subjects in these eight very different kinds of cities. The commonality of attitudes toward the "most serious crimes" was high among all respondents, but among the various subgroups of mental health professionals there was substantial agreement ($p>.50$) in 39 out of 48 possible rating categories—there was agreement between mental health professionals and other respondents in 32 out of 48 categories. Mental health professionals, however, ranked the offense of "perceived sexual misbehavior *not* involving violence" significantly lower in terms of seriousness than did other respondents. Mental health professionals in Tokyo ranked nonlethal, nonsexual violence as significantly higher in terms of seriousness than did other respondents, as did those in Athens public dishonesty. Mental health professionals in Paris ranked theft significantly lower as a "worst crime" than did other respondents.

In terms of "what to do about crime," there were greater differences between mental health professionals and other respondents. Almost two-thirds of the total group of respondents endorsed an organized, problem-solving strategy; all mental health professionals except 1 psychologist in Bombay strongly endorsed this orientation. Holding the demographic variables of geographic location, age, sex, socioeconomic status, and degree of expertise constant, mental health professionals showed significantly higher loadings on what might be called the "public health" factor, i.e., an approach involving general social programs to prevent or reduce antisocial behavior (directly or indirectly), more information and research, and (especially) treatment, rehabilitation, and/or reeducation processes. Judgmental, pessimistic, and distorted responses were significantly less common among mental health professionals. Psychiatrists and psychologists showed significantly lower adjusted loadings on the "traditional-moralistic-punitive" factor, although nurses as a group significantly overendorsed traditional values and a concern for retributive justice. Mental health professionals also significantly overendorsed the otherwise low-ranked concern for humaneness per se. General social programs of prevention were favored significantly more often by mental health professionals in St. Louis and significantly less often by those in Bombay and Tokyo.

Discussion

In terms of ranking the "most serious crimes," mental health professionals throughout the world tend to have attitudes similar to those of other persons in their geographic location: like the majority of respondents, they are most concerned about crimes of violence, theft, exploitation, and public dishonesty. Perceived strategies for social control of crime, however, involve variables that are related primarily to education, occupation, and degree of involvement and/or expertise. But even more than other respondents of the upper socioeconomic and expert classes, mental health professionals tend toward a strong emphasis on an organized, problem-solving approach, including research, programs of prevention and defense, and treatment and rehabilitation. Data from previous studies indicate that persons from lower socioeconomic classes are most likely to hold negative attitudes toward rehabilitation and treatment procedures, although they have the highest rates of conviction for crime. Since mental

health professionals are most likely to endorse nonpunitive preventive and therapeutic strategies, they must expect antagonism, then, not only from the offenders themselves but from the larger body of lower and middle-class, uninformed, and uninvolved persons who endorse more traditional, moralistic approaches. A majority of people, however, especially mental health professionals, wants an organized, step-by-step problem-solving strategy. Our previous data clearly show that those people closest to the action most want more facts, more careful analysis, and more knowledge before proceeding with action programs. To help provide such information and research data on which to base a problem-solving strategy, perhaps more psychiatrists must join the group most emphasizing that need—those who are involved.

Anticholinergic Psychosis in a Bilingual: A Case Study

BY EDWARD LASKI, M.D., PH.D., AND ELISABETH TALEPOROS, PH.D.

There has been an increasing number of reports concerning "atropine psychosis" or "anticholinergic delirium" following either intentional or accidental ingestion of psychotropic medications with marked parasympatholytic properties (1). The physician must always be aware of this possibility in patients being treated with tricyclic antidepressants, neuroleptics, antiparkinsonian agents, and especially the combinations of these drugs that are common in psychiatric treatment. The signs and symptoms of this toxic state may vary dramatically from obvious peripheral and autonomic features (mydriasis, xerostomia, hyperpyrexia, flushing, and tachycardia) to a florid anticholinergic syndrome with hallucinations, psychotic behavior, impaired sensorium with marked confusion, and, ultimately, coma and death. Proper treatment with a cholinesterase inhibitor such as physostigmine salicylate, which is capable of reversing both peripheral and central anticholinergic effects, has often dramatic and sometimes lifesaving results.

We would like to describe the case of a bilingual schizophrenic patient who presented with clear signs of such a delirious psychosis. His symptoms in the toxic state included the sudden development of auditory hallucinations in his native language. Although it has been noted that stress or disease can be related to language regression, the aspect of psychopathological bilingualism discussed here has rarely been commented on in the literature, and only a few recent case reports have emphasized its importance (2–4).

Case Report

The patient, a 13-year-old Hispanic male, was admitted to the adolescent psychiatric ward of Bellevue Hospital on petition by the New York City Bureau of Child Welfare. Charges of physical and sexual abuse had been brought against the patient's 45-year-old father, an unemployed alcoholic. The patient, the second oldest of seven siblings, had come to New York City from Puerto Rico 4 years previously.

Before this hospitalization, the patient had been referred to a psychiatric clinic at another hospital because of constant "acting out" in school (truancy and fighting with peers and teachers). He was in psychotherapy and diazepam was prescribed. However, he became more anxious and guarded, and during the week before his admission to Bellevue he threatened to take all of his pills. He admitted that his father, while intoxicated, had forced him to perform "certain sexual acts" one night. The treating psychiatrist

thought the boy was frankly psychotic and insisted on hospitalizing him.

On admission to our service, the patient's appearance was that of a handsome, frightened young man who made minimal eye contact and kept picking at his fingernails. His command of English was good, but his speech was extremely guarded. His affect was constricted in range and depth but appropriate to the situation. His mood was anxious and depressed. The patient admitted having auditory hallucinations in English: he said that a devil was calling him "faggot" and saying "I'm going to get you." He thought he heard people around him calling his name. His sensorium was clear and there was no history of alcohol or drug abuse. Results of the medical examination were within normal limits.

The patient was diagnosed as having a schizophrenic reaction, paranoid type. Treatment was begun with chlorpromazine, and after 2 weeks he was on a maintenance dose of 600 mg p.o. h.s. His hallucinations had subsided entirely. Because of moderate cogwheel rigidity, benztropine mesylate, 2 mg b.i.d. and h.s., was added during the third week. After 2 days, the night nursing staff noticed that the patient was restless, had difficulty sleeping, and mumbled to himself. The next day he was wandering deliriously around the ward. He was disoriented, hallucinating, and spoke only in Spanish; he described hearing a devil telling him, "Yo te voy a coger" (I'm going to get you).

Physical examination revealed that his pupils were mydriatic and poorly reactive to light; he had dry skin, a normal temperature, mild hyperreflexia, diminished bowel sounds, and tachycardia (120 beats/minute). An ECG was started and 0.5 mg of physostigmine salicylate was administered subcutaneously three times in 30 minutes. His sinus rate returned to 80 per minute, and his bowel sounds increased. The patient dramatically reverted to English, describing his hallucinations vividly. He complained of the urge to defecate and of mild nausea. His delirium subsided. He was kept drug-free for the next 24 hours and was then maintained on chlorpromazine, 300 mg h.s., without any recurrence of his symptoms.

Discussion

Bilingualism and its relation to psychopathology have received little attention in the general research or clinical literature. Psychological studies of bilingualism have been concerned primarily with implications for cognitive functioning and learning (5). Most psychiatric studies of language in pathology have been limited to discussions of the content of schizophrenic language and its relation to thought disorders (6). The case we have described highlights the potential importance of combined efforts in these relatively unallied areas of investigation.

In one of the few attempts to combine psychiatric observation with research on bilingualism, Hemphill (7) described auditory hallucinations in South African polyglots. True polyglots, who are equally proficient in at least two languages, reported auditory hallucinations in the first language learned (the primary or mother tongue). However, those polyglots whose hallucinations appeared to be drug induced reported auditory hallucinations in all languages known to them. Hemphill contrasts the hallucinations of true polyglots with those of "refugee" polyglots who emigrated and were forced to learn a new language. Their hallucinations (generally of a persecutory nature) were reported only in the second language, and often were denied by the patients when they were questioned in their primary tongue.

Marcos and associates (8) compared clinical judgments of the severity of psychopathology when patients were interviewed in Spanish, their primary tongue, and when they were interviewed in English, their second language. Although no specific differences were found for hallucinations per se, the estimates of total psychopathology were greater when patients were interviewed in English. This finding suggests that these patients were probably refugee polyglots.

The case we have reported presents a somewhat different problem for interpretation. The patient behaved differently at different times; the language he used to describe his hallucinations depended on circumstance. Like refugee polyglots, this patient initially had persecutory hallucinations in his second language. As he improved, his hallucinations subsided and he seemed relatively free of schizophrenic symptoms. Shortly before his discharge he developed a toxic reaction to medication, and while the content of the hallucinations remained the same, they appeared and were reported only in Spanish.

It is possible that this patient lost some of his adaptive coping mechanisms as a result of the drug-induced psychotic state. His delirium is consistent with a picture of temporary loss of recently learned material, including perceptions of his immediate environment and ability to communicate in his relatively new language. Once the toxic reaction had abated, the patient's general adaptive mechanisms were restored, and he returned to his normal level of functioning in his second language.

An alternative explanation is that the patient experienced two different states of arousal. Less vigilance and a lowered level of arousal in the toxic state may account for his reversion to his mother tongue.

The findings presented indicate the need for further investigation and additional documentation of this kind of clinical observation. It is not possible to design controlled experiments, but clinical observations of this type may provide researchers in the fields of bilingualism and psychopathology with directions for answering basic questions in their individual areas, as well as with potential links between them. This clinical phenomenon has implications for those studying the relation of bilingualism to brain function, memory storage, and information processing, as well as to

those interested in linguistic and paralinguistic aspects of psychiatric phenomena.

Do Tricyclic Antidepressants Enhance Adrenergic Transmission?

BY ALAN FRAZER, PH.D., AND JOE MENDELS, M.D.

It has been suggested repeatedly that the tricyclic antidepressants exert their effects by blocking the neuronal reuptake of biogenic amines (norepinephrine and/or serotonin), thereby increasing the amount of neurotransmitter available to act at postsynaptic receptors and overcoming a hypothesized amine deficiency. Most of the evidence for this theory has been derived from studies of the acute pharmacological actions of these drugs, either after a single injection or by examination of in vitro effects. Since it is widely believed that the tricyclic compounds do not exert a significant therapeutic effect until they have been administered for 10–14 days or longer, it is surprising that relatively little attention has been directed toward their pharmacological actions after chronic administration. The available information suggests that tricyclics initiate effects that are different from, and perhaps opposite to, their acute effects. As is discussed below, such effects may be compensatory changes to the acute pharmacological actions of tricyclics.

In the course of a continuing series of studies dealing with this question (1), we have noted a late-developing pharmacological action of desmethylimipramine (DMI) that is relevant to the functional activity of the noradrenergic system.

Male Sprague-Dawley rats (200–300 g) were given intraperitoneal injections of DMI (5 mg/kg) once daily for either 4, 11, or 18 days. Control animals received intraperitoneal injections of isotonic saline solution for corresponding time periods. Twenty-four hours after the last injection of the series, the rats were decapitated. Procedures used for preparation of cerebral cortical slices, labeling with ^{3}H-adenine (10μCi/ml), and determination of ^{3}H-adenosine 3′,5′-monophosphate (cAMP) in the slices have been reported previously (1). Data from cortical slices of the three groups of saline-injected rats were not significantly different and have therefore been combined to form a single control group.

From table 1, it can be seen that DMI treatment did not significantly alter the basal accumulation of cAMP in cerebral cortical slices. In contrast, DMI treatment significantly reduced the net synthesis of cAMP stimulated by norepinephrine (NE) when the treatment lasted for more than 4 days.

As noted above, enhancement of adrenergic or serotonergic neuronal activity, as a consequence of tricyclic-induced blockade of amine reuptake (2), is the pharmacological effect to which the therapeutic effect of tricyclics is most often ascribed. Based on this idea, we explored initially the effect of treatment with imipramine given for 5 days on NE-stimulated cAMP net synthesis in cerebral cortical slices (1). The expectation was that blocking amine reuptake would cause an exaggerated response (i.e., stimulation of cAMP) to NE. However, the response to NE was reduced. Similar observations have been reported by others (3, 4), and it is apparent the administration of tricyclics does, over time, produce a diminished responsiveness to NE. This diminished response produced by exogenous NE after *chronic* tricyclic treatment is the opposite of the effect that would be predicted on the basis of blockade of amine reuptake.

There are several other pharmacological effects of chronic tricyclic treatment that might attenuate the postulated enhancement of adrenergic transmission produced by these drugs. Segal and associates (5) reported that in rats treated with DMI for 8 days and killed 24 hours after the final injection, the activity of

brain tyrosine hydroxylase, the rate-limiting enzyme in catecholamine biosynthesis, was reduced significantly. This may account for the reports that chronic treatment with tricyclic drugs lowers brain concentrations of NE, whereas acute treatment has no such effect (6).

It would be incorrect to assume that the lowered concentration of brain NE observed after chronic treatment with tricyclic drugs necessarily indicates diminished activity of NE-containing neuronal systems, as there need not be a correlation between amine concentrations and functional effects. Therefore, studies of the effect of tricyclic treatment on the "turnover" of NE may provide a better correlation with activity in NE neurons. Acute administration of tricyclic drugs reduces amine turnover, but chronic treatment with imipramine in rats accelerated the disappearance of radioactive NE from brain (6). Schildkraut and associates (6) speculated that enhanced turnover of NE after chronic treatment with imipramine might result in greater availability of NE to adrenergic receptors despite reduced brain NE concentration. In other words, chronic tricyclic treatment would still result in enhanced adrenergic transmission.

An alternative interpretation of data on NE turnover arises from our studies of the effects of chronic tricyclic treatment on NE-induced responses in brain tissue. The diminished effects produced by NE in rats given tricyclic drugs chronically may be due to the development of adrenergic receptor subsensitivity. The development of receptor subsensitivity may be viewed as a compensatory change to the presence of sustained elevated concentrations of NE in the synaptic cleft—a consequence of DMI blocking amine reuptake. It is possible decreases in adrenergic receptor sensitivity lead to a second compensatory change, namely, an increase in amine turnover, in much the same way that drug-induced blockade of adrenergic receptors produces an enhancement of turnover in adrenergic neurons (7). If this interpretation is correct, then tricyclic-induced alterations in presynaptic neurotransmitter metabolism would be related inversely to activity at the postsynaptic receptor site. The point to be emphasized is how difficult it may be to distinguish primary pharmacological effects from secondary compensatory ones.

It is clear that the tricyclic drugs produce multiple effects at the adrenergic synapse, and it seems premature to assume that any one of these interrelated responses is in itself the crucial factor in mediating the therapeutic action of these drugs. At this stage we still do not know the net effect of chronic treatment with tricyclic drugs on adrenergic transmission. There are short-term effects that appear to enhance this activity, while some long-term effects may diminish it. The net effect remains unknown and must be resolved in future studies. It is intriguing to speculate that there may be an association between the long-term tricyclic-induced effects on adrenergic responses and the apparent delay in development of therapeutic response. The fact that both require time to develop may be coincidental or it may suggest an important relationship. Perhaps the "tolerance" and "rebound" effects on REM sleep seen with the tricyclic drugs (8) may reflect long-term changes in receptor sensitivity induced by these agents. Alternatively, the long-term changes in adrenergic responsiveness may be deleterious, serving to attenuate the results produced by the acute (therapeutic?) effect of the tricyclics on amine reuptake.

These crucial questions remain unanswered. However, it is clear that it is necessary to completely reevaluate the relationship between the clinical effects of the tricyclics and their actions on biogenic amine systems.

Coincidental Improvement in Asthma During Lithium Treatment

BY SUHAYL J. NASR, M.D., AND ROBERT W. ATKINS, M.D.

The simultaneous occurrence of two illnesses in the same individual offers a unique opportunity to learn about both illnesses. It has long been suspected that emotional factors contribute to asthma, and in a recent review Knapp and associates (1) suggested a strong correlation between mood disturbances and asthmatic attacks. The two case reports below illustrate another facet of this correlation as well as unexpected improvement in asthma following administration of lithium carbonate for concurrent manic-depressive illness.

Case Reports

Case 1. The patient, a 39-year-old married woman with three children, began having psychotic episodes in 1969. She carried the diagnoses of chronic schizophrenia and schizo-affective schizophrenia and was treated with various phenothiazines and butyrophenones. She experienced several relapses on this regimen and was admitted to the Strong Memorial Hospital, Rochester, N.Y., in December 1975 and again in March 1976. At the time of her second admission, the staff diagnosed her as manic-depressive, manic phase, and started her on lithium carbonate. Since that time, the patient has experienced no recurrence of her psychotic symptoms and has resumed normal functioning. The patient spontaneously reported in November 1976 that she has not needed any antiasthmatic medication since she started on lithium carbonate. She also mentioned that her antiasthmatic medication, particularly the xanthines, previously precipitated those hypomanic episodes that led to her hospitalizations. The past year has been the first since 1969 that she has had no psychotic episodes and no asthmatic attacks. She has been on lithium carbonate, 600 mg b.i.d., and has received no other form of therapy. Her serum lithium level has ranged between 0.6 and 0.9 mEq/liter.

Dr. Nasr is Chief Resident and Dr. Atkins is Professor, Department of Psychiatry, University of Rochester Medical Center, Rochester, N.Y. 14642.

The authors would like to acknowledge the assistance of Drs. Haroutun Babigian and Mark Proctor.

Case 2. The patient, a 65-year-old married man, began to have psychotic episodes in 1949. He has had four episodes since that time and has received varying diagnoses of acute psychotic episode, psychotic depressive reaction, manic-depressive, manic phase, and manic-depressive, depressive phase. His last admission was in March 1976, when he was started on lithium carbonate. The patient has also had asthma for several years and is severely allergic to iodine. He reports that since he began to take lithium he has not had any asthmatic attacks and has used his antiasthmatic medications only for his occasional episodes of wheezing. He is presently well maintained on lithium, 300 mg b.i.d., with serum levels ranging between 0.8 and 1.0 mEq/liter.

Discussion

These two cases illustrate the good response of concurrent manic-depressive illness and asthma to one pharmacological agent, lithium carbonate.

Patients with asthma experience acute recurrent exacerbations of their illness and are usually symptom-free in the intervening periods, which is also true of manic-depressive patients, although each episode is significantly longer than that in asthma. In both illnesses persistence of the symptoms over longer periods of time leads to significant reduction in the psychological, social, and medical functioning of the individual.

Tricyclic antidepressants have a well-established role in the relief of depression (2). They are also suspected of exerting a beneficial effect in asthma through their anticholinergic, antihistamine, and catecholamine-blocking properties (1). Amphetamines produce immediate and short-lasting relief of depression. Epinephrine plays a strikingly similar role in acute asthmatic attacks.

Xanthines, steroids, and epinephrine, the drugs of choice in asthma, act through increasing available cyclic adenosine monophosphate (cAMP) (3). Prostaglandins, particularly the balance between PGE_1 and $PGF_{2\alpha}$, have been suspected of playing an important role in the pathogenesis of asthma (4). Lithium has

been proven effective in the treatment and prophylaxis of manic-depressive illness (2). A variety of modes of interaction between lithium, prostaglandins, and cAMP have been described. Murphy and associates (5) described inhibition by lithium of the PGE_1-mediated increase in cAMP. Horrobin (6) suggested a modulation role for lithium in prolactin-induced prostaglandin synthesis. Lithium has also been shown to increase glucagon-stimulated cAMP excretion (7). We suggest that lithium modulates the balance between PGE_1 and $PGF_{2\alpha}$ and cAMP and cyclic guanosine 5′-monophosphate, thus aborting the clinical manifestations of asthma in our patients.

Conclusions

We have presented two unusual cases of concurrent asthma and manic-depressive illness responding well to a single agent, lithium. This report raises several questions about the interactions among lithium, prostaglandins, and cyclic nucleotides. Patients with asthma and manic-depressive illness provide a unique opportunity to study these interactions.

Increased Palpebral Aperture in a Patient Receiving Amitriptyline

BY DAVID J. GOODE, M.D.

Exophthalmos has not been reported as a side effect of amitriptyline. This paper will report the case of a 57-year-old man being treated for depression with amitriptyline who had a markedly increased palpebral aperture that resembled exophthalmos, although there was no protrusion of the orbit. The phenomenon appeared 3 days after amitriptyline was started at a dose of 75 mg/day and disappeared within 2 days after the drug was discontinued. The increase in palpebral aperture was accompanied by a reported decrease in depressive symptoms. The similarity of this idiosyncratic side effect to inhibition of reserpine-induced ptosis in experimental animals, one of the primary catecholamine-related effects common to all antidepressant drugs, is striking.

Case Report

Mr. A, a 57-year-old divorced man, was seen at a local mental health center in April 1974, for somatic complaints related to a depressed state. Since November 1973, he had consulted numerous emergency rooms for chest and abdominal pain and had received several drugs (he did not remember what they were). During early 1974, he developed increased insomnia, loss of libido, frequent crying spells, feelings of sadness, and lost approximately 23 kg. He had no history of alcoholism, drug abuse, or psychiatric consultation, and there was no known history of depression or alcoholism among first-degree relatives. He was placed on thioridazine, 150 mg/day, at the time of initial consultation, but he experienced little relief. In June 1974, he was admitted to the inpatient psychiatry unit at the University of Chicago because of a suicidal gesture in which he inserted a knife into an electric socket but was not hurt.

During hospitalization he was observed to be moderately hypertensive and was treated successfully with a combination preparation of 50 mg of triamterene and 25 mg of hydrochlorothiazide twice a day. His depression gradually improved on perphenazine, 24 mg/day, and supportive and milieu therapy. The patient gained 3 kg during his hospitalization and his somatic complaints decreased. An episode of gastric bleeding during hospitalization was found to be secondary to atrophic gastritis. Neurological examination was normal except for a minor residual Bell's palsy on the left.

When this work was done, Dr. Goode was Assistant Professor of Psychiatry, University of Chicago, Pritzker School of Medicine, and Chief of Research, Ward 10-W, Laboratory of Biological Psychiatry, Illinois State Psychiatric Institute, Chicago, Ill. He is now Associate Professor, Department of Psychiatry, Bowman Gray School of Medicine, Winston-Salem, N.C. 27103.

On the patient's discharge, the above medications and simethicone tablets were prescribed.

After his discharge, he was treated at the local mental health center; the perphenazine was replaced by thioridazine, 200 mg/day. He did moderately well but continued to appear somewhat depressed. In January 1975, he was placed on amitriptyline, 75 mg/day in divided doses, and the thioridazine was discontinued at that time. The patient reported some subjective improvement in mood within 3–4 days. However, his family and friends noted that his eyes seemed to be bulging. The patient did not complain about his eyes and in fact did not seem to notice the apparent exophthalmos. On examination, his eyes were widely open at rest, with sclera visible above and below the irides. However, the eyes were not protuberant and looked normal when closed. There were no other symptoms or side effects reported and the patient said his depressive symptoms had improved. Pulse rate and rhythm were normal, and the thyroid was not palpable. The amitriptyline was discontinued and thioridazine was reinstituted immediately. The apparent exophthalmos completely disappeared within two days after discontinuation of the amitriptyline. The patient was on no other medication, having failed to renew his diuretic prescriptions several weeks before institution of amitriptyline.

Discussion

The apparent exophthalmos in this patient did not involve the protrusion of the orbit that is seen in true exophthalmos, but the palpebral aperture was dramatically widened. There was no clinical evidence of thyroid disease, palpebral pain or edema, or scleral injection, and the symptom disappeared within 2 days of discontinuation of amitriptyline.

The widening of the palpebral aperture produced by amitriptyline in this patient might be analogous to the capacity of antidepressant drugs to inhibit reserpine-induced ptosis in the rat (1–4). The action of these drugs in this animal model is based on blockade of catecholamine reuptake or metabolic deactivation, combined with the catecholamine-releasing effects of reserpine, which makes larger amounts of catecholamine accessible to receptor sites (4). Reduced catecholamine availability has been postulated as a primary component of depressive illness (5). In the case I have reported a depression-related reduction in available catecholamine might lead to secondarily increased catecholamine receptor sensitivity, which could result in an exaggerated catecholaminergic effect caused by amitriptyline through inhibition of catecholamine uptake combined with heightened receptor sensitivity. However, in the experimental situation the antidepressant agent is more effective in reversing ptosis when it is given before catecholamine depletion by reserpine. When antidepressants are given after administration of reserpine, which seems more analogous to the depressed state, they are less effective or ineffective in reversing ptosis. Moreover, the increase in the palpebral aperture observed in this patient was not a restoration of a narrowed palpebral aperture to normal as is seen in the rat, but rather was an obvious increase above normal limits. An idiosyncratic sensitivity of palpebral adrenergic receptors may have also played a role in the etiology of this apparent exophthalmos.

A second possible mechanism involves interaction of the effects of the antidepressant with those of the phenothiazine that the patient was taking immediately prior to institution of amitriptyline. Phenothiazines block peripheral receptor sites for norepinephrine and epinephrine, which may lead to compensatory increases in peripheral adrenergic activity (6). Decreasing levels of phenothiazine-induced adrenergic receptor blocking activity, combined with compensatory increased adrenergic activity and blockade of catecholamine reuptake by amitriptyline, could also result in such an exaggerated catecholaminergic effect by amitriptyline.

LETTERS TO THE EDITOR

This section contains reactions to Journal *articles, statements of opinion, comments on Association activities, requests for information, etc. Letters should be submitted in duplicate to the Editor, who makes all decisions regarding publication. Letters must be typed double spaced throughout and should not contain more than 500 words and 5 pertinent references. An Unfair Portrayal of Psychiatry

SIR: I am sure that many of my colleagues recently witnessed the so-called news report on ABC television entitled "Medicine and Madness." By using the most esoteric and tangential evidence possible and including, it seemed, every medical dissenter in the current ranks of psychiatry who could be jumbled into an hour (an approach perhaps epitomized by the classification of E. Fuller Torrey as a typical "ward psychiatrist"), ABC managed to dazzle our eyes with erudite expatients waxing eloquently on the evils of Thorazine (although we were not shown any of these people prior to their "poisoning"), expatients treated with ECT whose lives were shattered by irreversible losses of memory, and probably the most outrageous case of tardive dyskinesia I have ever seen.

I would like to answer Howard K. Smith and the tiny group of producers in New York with a series of questions and problems that I face daily:

1. What would you have us do with a man who believes he is Napoleon, a girl who attacks her parents in the belief they are Jesus Christ's assassins, or an elderly woman who washes her hands 200 times a day, believing they are contaminated? Are these people simply exhibiting a rather odd type of individuality?
2. If you wish to allow such a depth of personal variance in what is considered normal, can you tell me how to get schools, police, lawyers, and almost all of my fellow nonpsychiatric physicians to stop sending me homosexuals, pedophiles, alcoholics, addicts, drifters, and anti-social characters, who are supposedly not "ill" in the classical sense?
3. Why have the populations of our institutions fallen so much since the inception of antipsychotics? How many millions did you not interview, who are willing to trade some physical side effects for the priceless gift of being released from the terrors of unseen voices, lost emotions, and untold millions of dollars in lost productivity?
4. Must I know how the human brain works in complete and cosmic detail to realize that the brain, consciousness, and subsequent emotions are somehow associated? Is a neurosurgeon to ask himself profound theological questions about what he is doing before he allows himself to operate on the brain? With untold misery and suffering in our institutions, I refuse to wait until my philosophical colleagues decide the relationship in its totality between the brain and personality before I take note of the facts that lithium seems to help mania and an extremely depressed person regains his appetite with the aid of antidepressants. However the medications work, I believe that any agent that keeps my patient from losing his family, his friends, his possessions, and his self-respect is worth the gamble.
5. How do you persuade someone not to be catatonic—by talking with them, by telling the family that this individual has his own way of doing things? Will the catatonic patient hire a "tutor" as Drs. Szasz and Torrey would have it? If I cannot find a specific neurological lesion, do I conclude the individual is not ill?
6. Because I use the label of schizophrenia, am I to blame for the ancient prejudices against the emotionally ill that reflect themselves in endless punitive ways? The term schizophrenia is no more pejorative in my mind than that which it denotes—a human being who hears voices that are not there, sees visions, and cannot seem to control his thinking.
7. Will you please feature on network television a story highlighting the research we are doing into the causes of emotional disorders?
8. Would you please remove the needless violence, sexual flamboyance, mindless comedy, and one-dimensional perfect parents from your nightly programs? These common nightly events are watched by countless millions of people who may be receiving faulty sensory input.

This program did the worst damage not to ourselves, but to the great number of unhappy people who may be contemplating some sort of therapy. By outlining extremes of current treatment and theory and depicting occasional excess, and presenting these as the norm, it leaves great doubt in the minds of all who may need help. This is the worst form of journalistic tyranny.

EVAN M. TORCH, M.D.
Augusta, Ga.

Editor's Note: Hundreds of letters and telegrams, including an official protest from the American Psychiatric Association, were sent to ABC authorities to protest this vicious attack upon psychiatry and its patients.

GHB and GABA

SIR: We were very interested in the article by Daniel P. van Kammen, M.D., on "γ-Aminobutyric Acid (GABA) and the Dopamine Hypothesis of Schizophrenia" (February 1977 issue). Certainly, GABA involvement in schizophrenia is a major issue.

We are currently involved in this problem, and we would therefore like to point out that a useful way to increase the functional activity of GABA in the brain that did not appear

in appendix 1 of Dr. van Kammen's paper is the administration of sodium γ-hydroxybutyrate (GHB), which is a precursor of GABA that crosses the blood-brain barrier.[1]

This drug, which is used as an anesthetic in France, was released by Laborit and colleagues (1). Curiously, its use in psychiatry has been quite limited. One possible use could be in the treatment of sexual dysfunction.

We think that Gamma OH deserves to be investigated by well-controlled studies.

F. PLANTEY, M.D.
Nantes, France

[1]This drug, under the name Gamma OH, is marketed by EGIC, 19, Avenue Morane Saulnier, Meudon La Foret 92360, France.

Dr. van Kammen Replies

SIR: Dr. Plantey is quite correct in suggesting that the effects of γ-hydroxybutyrate (GHB) in schizophrenia should be examined in a well-controlled study. However, its effects are not mediated through GABA.

GHB, like its precursor γ-butyrolactone (GBL), is a minor GABA metabolite with a short half-life (1). GHB increases delta sleep and decreases REM latency (2). It has been reported that some schizophrenic patients have decreased delta sleep. GHB inhibits impulse flow in dopamine pathways, which decreases dopamine release (3); it also induces dopamine synthesis and decreases release without affecting monoamine oxidase or catechol-*O*-methyltransferase (4). Studies done by Gianutsos and associates (5) suggested specific presynaptic dopamine effects in vivo. GBL potentiates haloperidol-induced catalepsy, can affect tyrosine hydroxylase activity, and has some antiamphetamine effects. It slows the disappearance of dopamine but not that of norepinephrine in rats after α-methyl *p*-tyrosine administration. Dopamine agonists inhibit dopamine accumulation following GBL treatment.[1]

As early as 1961, Laborit's group (6) and Danon-Boileau and associates (7) reported that GHB had antianxiety and potential neuroleptic effects in psychotic patients. We are studying GHB for its alleged antidopamine and antipsychotic properties in our schizophrenic patients. One patient, who has had chronic paranoid schizophrenia for eight years and has a low tolerance for antipsychotic neuroleptics, developed akathisia that lasted up to one week after discontinuation of GHB. Another patient who had been psychotic for three years lost all symptoms. A third patient with catatonic schizophrenia of nine years' duration had an amphetamine-like response, with euphoria and increased sexual feelings (a behavior she had not exhibited previously), but became more psychotic during the GHB administration. Our preliminary data indicate that GHB may have some effects on psychotic behavior. The extent to which the effects of GHB and GBL in man are dopamine-specific is currently unknown.

Motivations for Drug Treatment

SIR: Robert J. Harford, Ph.D., and associates are to be congratulated for their attention to a very significant and neglected area in treatment research in "Effects of Legal Pressure on Prognosis for Treatment of Drug Dependence" (December 1976 issue). However, I feel that they have stretched their interpretations more than the data allow.

The crux of my concern rests with their definition of legal pressure ("legal pressure was defined to exist if the applicant reported being on probation, on parole, or awaiting trial at the time of application"). Leaving aside the question of whether what the applicant reported was the truth, I suggest that being on probation or parole or, to a lesser extent, awaiting trial, may actually involve very little if any implicit coercion for many persons. The authors noted this possibility but seemingly ignored it when generalizing their conclusion that legal pressure does not facilitate treatment. For example, in Seattle it is not at all uncommon for a person on probation (when a condition of probation was that he enter into and successfully complete a treatment program) to leave the program early, knowing that when he agreed to enter the program charges would in effect be dropped if he quit, and that there would be no sequelae to this violation of his contract with the court.

Just being on probation, parole, or awaiting trial cannot be considered to be legal pressure. However, assuming that legal pressure did exist for some subjects, it would be useful to describe what the exact dimensions of the pressure were. Obviously, a reduced possession charge that may result in 90 days in jail is insignificant compared to an armed robbery charge associated with a drug heist and carrying a possible 20-year jail sentence.

In addition, I think that it is quite chancy to suggest that rehabilitation success may be usefully or solely measured by program retention. It is my clinical impression that a person can be an involuntary member of a treatment program, leave before the prescribed completion time, and still possibly benefit through an improvement in future social behavior. Admittedly, there are no hard data in this area.

Motivation is a ponderous word. Strictly speaking, I believe few if any people "volunteer" (without any coercion) for any treatment, and I am not aware of any definitive way to measure "intrinsic motivation." Motivation may be internally or externally derived, yet I believe that clients can be successfully treated in either case. The involuntary client or patient may have more difficult and tenacious problems and dyssocial character traits simply by virtue of the fact that he has already been charged with a transgression of social codes. If this is true he will probably be a more difficult person to work with and be more resistant to efforts to change his behavior.

I believe that most persons who are presently in discomfort (e.g., an addict with viral hepatitis, an alcoholic who is frightened that his wife will leave him if he doesn't stop drinking) are better candidates for treatment than those who have been convicted of an offense (trafficking in heroin, driving while intoxicated, etc.) and show no remorse about their behavior but "volunteer" for treatment because they are definitely concerned about the prospect of future incarceration. Consequently, given a choice between individuals who are still externalizing the source of their difficulty and have not fully adjusted to the fact that the problem is really their own and those who are truly interested and sufficiently pained by their positions to be open to behavioral intervention, I would choose the latter. However, if I had to work with the former, I would categorically prefer that treatment be preceded by a firm, well-understood contract between the client, the therapist, and the criminal justice system. Such an agreement actually begins the treatment process by holding both the client and the criminal justice system responsible for all of their behaviors, including their formalized intentions.

ROBERT B. FISHER, M.D.
Seattle, Wash.

Dr. Harford Replies

SIR: Dr. Fisher's point that some applicants who are on parole, on probation, or awaiting trial do not feel coerced into continuing treatment is well taken. Since legal pressure is the principal reason for their application, many choose to terminate treatment when their cases are resolved. On the other side of the ledger, some persons classified as voluntary admissions apply out of anticipated or imagined legal pressure that can be generated, for example, when a drug-using acquaintance is apprehended. If the expected legal consequences fail to materialize, these "volunteers" also are highly likely to terminate. There is no necessary one-to-one correspondence between the procedures used by the criminal justice system to generate legal pressure and the degree of compulsion perceived by individual addicts.

We endorse Dr. Fisher's suggestion concerning the usefulness of a quantitative measure of perceived legal pressure in clarifying the relationship between status in the criminal justice system and perceived legal pressure. However, lacking such a measure, we are not persuaded to abandon the assumption that applicants who are not involved with the criminal justice system experience less external pressure for treatment than those who are on probation, on parole, or awaiting trial. The links between criminal justice status, perceived legal pressure, and motivation in our report are *entirely* hypothetical. However, our inferences are buttressed by empirical research indicating 1) consistent differences in psychological characteristics between volunteers and nonvolunteers (1, 2) and 2) higher rates of illicit drug use during treatment by nonvolunteers than by volunteers (3, 4). These characteristics have been interpreted as indications of differences in motivation for seeking treatment.

We agree that in important respects retention is an inadequate measure of rehabilitative success. Several recent investigations have demonstrated that retention in drug abuse treatment is not correlated with any dimension of treatment outcome. In addition, time spent in treatment can produce negative effects as well as benefits, especially when adolescents with relatively minor criminal violations are placed in programs in which older criminal heroin addicts predominate. It was with these reservations in mind that we conducted our principal statistical analyses on the relationships between legal pressure and graduation rates. Graduation can be considered as a composite of the several indications of rehabilitative success as operationalized by clinical judgment. The assumptions underlying the subsequent retention analyses were stated clearly (p. 1400), and the inadequacies of the measure were acknowledged, at least implicitly, by our conclusion that "future research also should consider measures of rehabilitative success other than retention" (p. 1403).

Concerning Dr. Fisher's judgment that we overinterpreted the data, we can do no more than refer readers to the précis (p. 1399), quote the first paragraph of the discussion to the effect that our finding "*suggests the possibility* that legal pressure inhibits rather than facilitates treatment for addiction" (p. 1402, emphasis added), and cite the conclusion that "our findings *merely suggest* that legal pressure does not enhance the probability of successful rehabilitation" (p. 1403, emphasis added).

Memory Loss with Lithium Treatment

SIR: We would like to respond with some confirming data to the letter by George F. Bajor, M.D., entitled, "Memory Loss with Lithium?" (May 1977 issue). Our material comes

from follow-up interviews done with patients who were administered lithium under an experimental protocol during the years 1966–1975 (1, 2).

Of the 28 cases we have thus far reviewed, 7 patients, ranging in age from 21 to 56, who have all been on lithium for a period of years, have complained of memory loss that they associate with lithium treatment. This memory loss in most cases is described as an inability to recall details that interferes with daily functioning. All but 2 of these 7 patients had also received ECT at some point in the course of their illness; however, at least one patient who had received both treatments claimed to be able to distinguish the post-ECT memory loss from that associated with lithium.

We agree that this topic merits further investigation, perhaps using techniques such as those reported by Koh and associates (3–5) for the study of memory processes in schizophrenia.

Tricyclic Choice for Ill Elderly Patients

SIR: The discussion by C. Gibson Dunn, M.D., and David Gross, M.D., of factors involved in the use of tricyclic antidepressants in medically ill geriatric patients (Clinical and Research Reports, April 1977 issue) was to the point, but I question their choice of amitriptyline to treat a 71-year-old depressed man who had serious cardiac disease and was in need of a quinidine antiarrhythmic.

The well-known cardiovascular effects of tricyclics—orthostatic hypotension, conduction disturbances, tachyarrhythmias, congestive heart failure, and ST-T wave ECG changes—appear to occur most frequently with amitriptyline (1). In a patient with preexisting angina pectoris, extraventricular arrhythmias, first-degree A-V block, and ST-T wave changes, the choice of this particular drug is especially hazardous and probably ill-advised (1).

Furthermore, recent studies suggest that concurrent therapy with certain tricyclics and quinidine may increase the risk of drug-induced cardiac disturbances. In therapeutic doses, nortriptyline, an amitriptyline metabolite, prolongs atrioventricular conduction by selectively slowing the H-V interval demonstrated on His bundle recordings (2). Quinidine has the same selective effect. Imipramine also appears to possess similar quinidine-like properties (3). Coadministration of these agents is, therefore, likely to increase the hazard of drug-induced heart block (3), particularly in a patient who already manifests a first-degree atrioventricular conduction delay.

A more rational choice for such a patient is doxepin. Although some doubt still exists as to its relative clinical potency, cardiovascular studies of patients taking doxepin confirm its superior safety, even in the event of overdosage (1, 2, 4). Orthostatic hypotension, supraventricular tachycardia, conduction disturbances, and ECG changes occur less frequently with this tricyclic. His bundlegrams in patients on therapeutic doses and in cases of overdose reveal minimal delay in H-V conduction (2), suggesting less potential for adverse interaction with quinidine-like antiarrhythmics.

DANIEL R. WEINBERGER, M.D.
Boston, Mass.

Drs. Dunn and Gross Reply

SIR: We appreciate the opportunity to review the major points of our article:

1. It is important (and may be critical) to diagnose depression in the medically ill geriatric patient.
2. Active treatment of such depression is feasible.
3. Medication side effects must be considered and specific precautions taken to minimize morbidity. These precautions may include careful vital sign observation, serial ECGs, serial tests of pulmonary function and arterial blood gases, good pulmonary toilet, and others indicated by a patient's physical condition.

Although drug selection was not intended to be a focus of our article, we agree that doxepin would be a reasonable alternative to amitriptyline. The choice is not as simple, however, as Dr. Weinberger implies. Doxepin is recognized to be a much less potent antidepressant (1). Its effect on inhibiting the reuptake of biogenic amines at the synapse may be only one-third to one-half that of the other tricyclics. Snyder notes the following relative central anticholinergic strengths of the most frequently prescribed tricyclic antidepressants: doxepin, 1.0; imipramine, 1.9; amitriptyline, 3.7 (2). If we allow for the larger doxepin dosage to achieve a similar clinical effect in a severely depressed patient, we have lost much of the advantage claimed. This is not to argue against doxepin. Rather, we stress that repeated careful monitoring of vital functions, not excessive faith in any single drug, should

be the primary precaution when treating depression in geriatric patients.

A Computer-Based Lithium Library

SIR: Lithium salts are being widely used for the treatment and prophylaxis of bipolar affective disorder (manic-depressive psychosis). In addition, the effectiveness of this drug in more than 30 other illnesses is under investigation. In recent years the body of literature covering this field has expanded explosively and will soon exceed 4,000 articles.

In order to deal with this voluminous body of information in a way that provides rapid and complete access to the data base, we have adapted the "Great Paper Search" computer program[1] to create a computer-based lithium library.

As recently described (1), the library is an international index that is continually updated to keep abreast of recent developments; it currently contains over 3,000 articles. It can be thoroughly searched in a matter of minutes according to author, title, journal, and subject (key word). Any combination of these four headings may be searched simultaneously using Boolean "ands," "ors," and "nots" to define the limits of the search. We have on file all articles listed on the computer so that once a search has been conducted copies of pertinent articles can be obtained.

The program is now directly available to persons or institutions with access to a compatible computer terminal; those without access to a terminal can contact the Lithium Information Center by phone or mail (address: Lithium Information Center, University of Wisconsin Center for Health Sciences, 427 Lorch St., Madison, Wis. 53706; telephone: (608) 262-1674 or 262-6314).

This service is readily accessible to psychiatrists and other interested professionals, and we hope they will avail themselves of it to obtain up-to-date, comprehensive and problem-specific information about lithium and its medical-psychiatric applications.

Finally, the "Lithium Librarian" should serve as a model that will allow development and implementation of similar systems covering other specialized subject areas of interest to clinicians and researchers.

Public and Private Psychiatric Care

SIR: "Problems in Analyzing the Comparative Costs of Private Versus Public Psychiatric Care," by Steven S. Sharfstein, M.D., and associates (January 1977 issue), highlights issues with which I have been groping.

My work with three community mental health centers and in private practice has convinced me that the two methods of care, while overlapping, really serve two different types of patients. In the CMHCs I can handle chronic schizophrenic patients, most alcoholics, and multi-problem families better than I can in a private setting because there are many people and treatment methods available to apply to these problems. However, the CMHCs fail miserably when they try to deal with neurotic patients because the centers have too few people trained to do insight psychotherapy and because funds are too limited to allow fully trained therapists enough time to help such patients. At times I feel forced to cheat clinic patients because I must listen to them for only half an hour a month instead of really treating them.

Perhaps one problem is that we are unwilling to state clearly what we can and cannot do. We can assist a team in keeping a chronic schizophrenic out of the hospital and in keeping an aggressive alcoholic from brutalizing his wife, but the best therapist in the world, even given unlimited visits, can cure neither one. We can see five neurotics ten times a year and really help none, or see one neurotic once a week for two years and save his marriage and help him get a better job. Perhaps the ultimate in double binds is the plan that allows 30 visits a year. It allows abuses of supportive treatment and castrates almost all insight therapy. It is a procrustean bed, which looks like a compromise but ultimately escalates costs and prevents benefits.

WILLIAM L. CLOVIS, M.D.
Philadelphia, Pa.

Dangers of Minimal Drinking

SIR: The letter by E. Wayne Massey, M.D. (March 1977 issue) on "Neurology of the Nonalcoholic" alcoholic was most interesting and highlighted the potential dangers of what might be considered by many to be only minimal drinking.

I am writing to point out a third serious danger, possibly more dangerous than the two mentioned by Dr. Massey, peripheral neuritis and cirrhosis of the liver. This third factor is organic brain damage; it is probably omitted from consideration because it is very difficult to detect in its early stages or if there is only a minor degree of damage. The common causative factor in all of these three potentially serious conditions is probably the aggregation of red blood cells (blood sludging), as described by Moskow and associates (1). As these authors pointed out, the aggregation of red blood cells blocks the circulation and creates anoxemia of the organs involved; the nervous system is particularly sensitive to this effect. Everyone working in the field of alcoholism ought to be aware of the phenomenon of blood sludging.

The concept of blood sludging has led to a logical form of therapy, i.e., use of anticoagulants to reduce the blood sludging. We have found this approach to be very helpful in patients with alcoholic brain damage (2) but do not know if it would be helpful in cirrhosis or in peripheral neuritis, although one patient with the latter condition did improve considerably.

A fourth potentially serious complication of alcohol intake is now becoming more publicized—damage to the fetus during the first trimester of pregnancy. Although the early studies of the effects of alcohol during pregnancy were done with chronic alcoholics, it is quite possible that even small amounts of alcohol may cause serious damage to the developing fetus if ingested at a critical developmental period.

ARTHUR C. WALSH, M.D.
Pittsburgh, Pa.

Dr. Massey Replies

SIR: I appreciate Dr. Walsh's response to my letter in the *Journal*. He was quite correct to point out another factor that is a danger of minimal drinking. I omitted organic brain damage because minor degrees are extremely difficult to detect and it is already well known that alcohol abuse can lead to it. My emphasis in the letter was on neurological entities that are often forgotten.

Blood sludging is indeed a possible factor in organic brain damage, although absolute proof is lacking in the literature. Since the cerebral system is so different from the peripheral one, one could not automatically assume that sludging of red blood cells was the causative factor in peripheral nerve disease even if it were proved the cause of changes in cerebral circulation. Work on cerebral vasculature sludging has been done at the University of South Carolina for 30 years, but results are difficult to determine when dealing with cerebral blood flow techniques.

E. WAYNE MASSEY, M.D.
Bethesda, Md.

Problems in Liaison Psychiatry

SIR: I have enjoyed the writings of James J. Strain, M.D., on how liaison psychiatry should work (1), including his article entitled, "The Medical Setting: Is It Beyond the Psychiatrist?" (March 1977 issue). However, in my study of a new psychiatric unit and department in a general hospital, I have found that his hopefulness is not warranted (2).

I fully agree with Dr. Strain that liaison psychiatry offers a broad, exciting field, and an opportunity to work closely with the rest of medicine. However, my study indicates that in actual practice things are not this simple. In my five-year experience with one psychiatry department, it went from active involvement with the rest of the hospital to a self-serving, independent psychiatric hospital that happened to be housed in a general hospital.

It has been my experience that when new medical and surgical procedures (e.g., aortic graft, kidney transplant, stomach dialysis for kidney failure, breast augmentation, total hip replacement, and now kidney dialysis) are introduced and being perfected, psychiatrists, as Dr. Strain stated, "are not only welcomed, but in some settings beseiged to collaborate in [patient] management." After these procedures become old hat and the operators more confident, psychiatry is generally ignored. (How many aortic transplants have psychiatrists been called in for in the past five years? How often is a psychiatrist called in to see patients with delirium tremens in an established alcoholism treatment unit?)

Dr. Strain sees only the tip of the iceberg. Fifty percent of the time of American psychiatrists is spent in private practice. He should not extrapolate his impressions from a large, organized setting and say they work or should work in other settings—they don't.

Since my study, I have personally visited or obtained data from 17 other hospitals with 200–400-bed capacities that have psychiatric units and departments; I found that all but one had had experiences like the one I described. The lone exception was looked on by third-party carriers as having custodial-type care and had a high rate of retroactive denial of payments. Hospitals in the 450-bed and over range tended to move in Dr. Strain's recommended direction. They tended to have psychiatrists as full-time hospital employees. Dr. Zigmund Lebensohn (personal communication) was critical of my findings and recommendations, but his figures from Sibley Memorial Hospital (357 beds) in Washington, D.C., indicated even less involvement by the Department of Psychiatry in liaison psychiatry than I found in my experience.

No one has discussed financial resistance to liaison psychiatry. Bertram Brown, M.D., pointed out that the cost of general medical services is sharply reduced after introduction of psychiatric services (3). The corollary is that the nonpsychiatric physician in private practice makes less money if a psychiatrist is called in. I would like to find out from Dr. Strain if in the setting in which he works there is any financial incentive to calling or not calling a psychiatrist for consultation.

Although Dr. Strain's article and book are informative and thought provoking, I feel his ideas are generally unworkable except in large institutions with psychiatric and nonpsychiatric physician employees.

ROBERT BENSON, M.D.
Seattle, Wash.

Dr. Strain Replies

SIR: I appreciate Dr. Benson's interest in our work and his evaluation of the feasibility of the program described in our book (1–3). Although Dr. Benson has accurately identified the dilemmas that may impede the implementation of such a program, his pessimism with regard to the future of liaison psychiatry is unwarranted; it has been our experience that these dilemmas are not insurmountable. I think that Dr. Benson's lack of clarity with regard to the appropriate setting for a liaison psychiatry program and the distinction between liai-

son psychiatry and psychiatric consultation may account for many of the questions and doubts he raises.

The teaching of psychological concepts would be regarded as a legitimate activity in a teaching hospital but might not necessarily be viewed as such in a community hospital. We view liaison psychiatry as a pedagogic pursuit that attempts to teach medical caretakers at every level of training about core issues in medical psychology, e.g., depression in the medically ill, psychopharmacology, psychological reactions to illness and hospitalization, with the expectation that in time the interns, residents, and other health care workers will provide most of the psychological care for their patients themselves.

We regard consultation and liaison psychiatry as separate and distinct activities. Although consultation is the cornerstone of our work, the teaching efforts of the liaison psychiatrist should ultimately enable the medical staff to offer adequate psychological as well as medical care to aortic transplantation patients, patients with delirium tremens, etc., themselves, rather than routinely referring such patients for consultation. Since 50%–80% of medically ill patients have primary psychological dysfunction or psychological dysfunction secondary to physical illness, psychological care must reside with the medical caretakers and not the psychiatrist. Furthermore, these findings underscore the need for wide dissemination of knowledge of the psychology of the medically ill among medical caretakers.

Dr. Benson's observation that psychiatry departments in general hospitals tend to become independent and self-serving over time is an astute one. He has identified a major dilemma of the liaison psychiatrist but, once again, we do not feel this problem is insurmountable. He needs to convince departments of psychiatry of the purpose of his mission in order to avail himself of the resources of the department to implement his goals. In the last chapter of our book we have spelled out ways in which this problem has been resolved at Montefiore. Although we have not yet achieved the ideal relationship with our own department of psychiatry, we do feel that such an alliance lies within our grasp. However, without a considerable liaison effort directed to one's own department of psychiatry and the hospital administration, the situation that Dr. Benson describes as almost universally prevailing inevitably occurs.

To illustrate, the primary goal of the liaison psychiatrist is to persuade the department of medicine to secure the psychological well-being of its patients. Once they have become convinced of the need for such care, staff members of the department of medicine have a right to expect the liaison psychiatrist to make it available, and they object with justification to the fact that patients may be deprived of the psychological care they urgently require because they do not live in a prescribed geographical area, are financially ineligible, or do not interest the psychiatric staff. The liaison psychiatrist, who is in a position to witness these inequities at first hand, is obliged to bring them to the attention of the department of psychiatry, lest he forfeit the relationship he has worked to establish with the department of medicine. However, he frequently disturbs his psychiatric colleagues by requests that they reexamine their modus operandi (3).

Dr. Benson has accurately targeted the source of financial support as a major dilemma facing the liaison psychiatrist. Although one can bill for a psychiatric consultation, one cannot bill directly for liaison psychiatry efforts. (This clearly shows that third-party payers and federal, state, and city legislatures see a compelling difference between classical consultation psychiatry and liaison psychiatry, regardless of how psychiatrists themselves may feel about this division.)

There are currently four sources of funding for consultation/liaison psychiatry: 1) routine reimbursement for the standard psychiatric consultation; 2) hospital and medical school teaching appointments for liaison psychiatric teachers; 3) faculty stipends, and to a lesser extent, fellowship stipends for liaison psychiatry trainees funded by the Psychiatry Education Branch of the National Institute of Mental Health; and 4) innovative funding approaches that draw on consultation monies to provide liaison teaching and training.

The Renal-Psychiatric Modular Unit at Montefiore is an innovative approach that incorporates measures making it economically feasible to create a training position for a liaison psychiatric fellow (fourth-year resident) who will provide psychological care on an ongoing basis for chronic renal patients. Public Law 92-603 specifically allows Medicare payments of up to $250 per year for direct psychiatric consultation services to all renal transplant patients, regardless of age, for one year after surgery. Our program has been able to recruit fellows who agree to provide direct services to a limited number of renal patients, the total fees generated by such services to be equivalent to the stipend customarily paid fourth-year (fellowship year) residents, and to devote their remaining time to teaching psychological medicine in exchange for training in this subspecialty (4).

Finally, since the liaison psychiatrist does not take over the patient, he is not a competitor for the medically ill patient; in fact, he should enlarge the practice of his medical colleagues, who will not only be more able to identify psycho-social-medical distress, but who will also be in a position to offer treatment within the ongoing context of their medical practice.

Ictal and Subictal Neurosis

SIR: I would like to make some comments regarding "Delinquency, Psychomotor Epileptic Symptoms, and Paranoid Ideation: A Triad," by Dorothy Otnow Lewis, M.D. (December 1976 issue). It has always taken courage to diagnose psychomotor epilepsy on the basis of symptoms alone in the absence of a corroborating EEG. Neurologists consistently deny the existence of the condition unless textbook symptoms are accompanied by abnormal EEGs. However, somewhere along the gradient of illness CNS events that are not severe enough to produce EEG changes are still capable of producing symptoms of spontaneous cerebral discharges.

Since both the limbic system and the temporal lobe are involved in the whole range of cognitive-emotional re-

sponses, it is obvious that some lesions in these areas may produce atypical manifestations, referred to as ictal and subictal neurosis (1). Many patients with such symptoms are considered to be psychoneurotics, psychopaths, or sociopaths, and are treated accordingly. Neurologists in such cases tend to confuse cause and effect—when an individual becomes aware of episodic, disruptive, acausal intrapsychic changes that may result in meaningless, asocial, or antisocial activity, he or she almost always experiences profound anxiety, and treatment of the accompanying anxiety or depression is then recommended.

Unless this "borderland" of epilepsy is recognized at the medical-school level, neurologists will continue to diagnose it as anxiety neurosis. Insufficient research has been devoted to the cognitive status of these episodically occurring percepts. Such neural activities are correlated with an immediately sensed quality; by giving them a symbolic representation, as psychiatrists are wont to do, a causal sequence is implied where none exists. The interviewer has to be cognizant of the fact that patients are aware of sensory data that they are unable to describe.

Beyond the theoretical interest of this phenomenon is a clinically important consideration. As a psychiatric consultant in an Army hospital I see many young men who are brought in as a result of violent or antisocial behavior. In a surprisingly large proportion of these instances, even a brief interview discloses a history of head injuries after which these men notice a change in behavior for which they cannot offer any explanations; in some cases there is a time lapse between the injury and such changes.

Dr. Lewis mentions that little work has been done on the prevalence and characteristics of the disorder in delinquents. Here I must disagree with her. There is a rich literature, which I mentioned in the bibliography of my book (1), and much work has been published since. The Dreyfus Medical Foundation, New York, N.Y., maintains the most complete file of information. Perhaps Dr. Lewis found so little reference to this syndrome because of the general reluctance to ascribe what appears to be a behavioral abnormality to discrete neurological pathology. Interactions between neurology and psychiatry in such cases require further work.

In some instances, discrete lesions, which are not always verifiable, of either the temporal lobes or parts of the limbic system may be behind the soft neurological and the pseudoneurological symptoms of psychopaths, persons with impulse disorders, hypochondriacs, and psychoneurotics.

One has to witness the nearly incredible authenticity of ictal automatisms to appreciate the intellectual effort psychiatrists must expend to avoid the trap of teleological reasoning. It requires a major reorientation of the thinking of both neurologists and psychiatrists to acknowledge the existence of this wide borderland.

Dr. Lewis Replies

SIR: I was pleased to receive Dr. Jonas's response to my paper. His experience with adults manifesting a variety of symptoms and behaviors complements our experiences with youngsters in trouble with the law. He raises important issues regarding the need to heighten the awareness of doctors in general and psychiatrists in particular to the existence of psychomotor phenomena and the need for psychiatrists to always take a meticulous medical history. I am grateful to him for sharing his experiences.

A Kudo for the Boards

SIR: Before I took the American Board of Psychiatry and Neurology oral examinations in Washington, D.C., I reread "Experiences of Psychiatry Board Exam Casualties: A Survey Report" by Martin R. Lipp, M.D. (March 1976 issue). I felt quite discouraged—I was working full-time and had an 18-month-old boy at home, which did not make studying for the Boards an easy task.

My husband and son accompanied me to the examination site. We found the hotel accommodations excellent. The registration was fast and Dr. Rudy's orientation was helpful. Busses were provided for transportation to the different hospitals, and the examinations were conducted according to schedule, with no delays. I passed the examinations and was certified in psychiatry.

To my colleagues who will be taking the examinations, I would like to say, do not be discouraged by "casualties." Let us hear more positive feedback from physicians who passed the Boards and found them to be quite a rewarding educational experience.

Tachycardia in Acute Schizophrenia: Assessment of Treatment Adequacy

SIR: Acute schizophrenia is often thought of strictly in terms of emotional and psychiatric symptoms, with no consideration of somatic signs. However, psychosis is often accompanied by signs of autonomic nervous system changes such as tachycardia, which can exist with no outward signs of agitation, nervousness, or anxiety. Tachycardia occurs in acute psychotic conditions such as schizophrenia and mania, and although it is not diagnostic of psychosis, its presence provides a fortuitous guide to the adequacy of treatment.

The mainstay in the treatment of acute schizophrenia is neuroleptic medications. By monitoring pulses several times a day in those psychotic patients who have elevated heart rates, the clinician can gain a reliable guide to the adequacy of the treatment. Tachycardia indicates insufficient treatment (usually inadequate doses of neuroleptics), while a normal pulse tends to indicate adequate therapy. This is true in spite of the fact that neuroleptic drugs, being anticholinergic, tend to increase heart rate.

In conclusion then, acutely psychotic schizophrenics often have elevated pulses, regardless of whether they are calm or agitated, and the heart rate decreases during adequate treatment with neuroleptic medications, despite their pharmacological tendency to increase heart rate.

We are currently in the process of conducting formal research on this observation and have started a pilot program

to assess pulse rates in acute schizophrenia and plot them against recovery rates.

Exhibitionism or Narcissism?

SIR: Marc H. Hollender, M.D., and associates described a patient purported to be a "striking case of a female exhibitionist" (April 1977 issue). Their patient, Ms A, is described with clarity and sensitivity, but her behavior does not seem "striking" and there are some reasons to doubt that hers is a case of "genital exhibitionism."

Essentially, Ms A, a stripper, is described as somewhat defective in reality testing and judgment, limited in emotional resources, and hungry for attention. When intoxicated she "flashes," exhibiting her breasts and genitals. Flashing is but one of a wide range of exhibitionistic behaviors that seem to abound in our culture (e.g., "mooning," "streaking," stripping, nude encounter groups, topless sunbathing, nudism). Ms A's flashing does resemble the behavior of the familiar male sexual variant. Yet flashing from doorways would appear to be commonplace in certain settings according to the descriptions of the activities of prostitutes in "red-light districts." Whether the motive for the behavior of these prostitutes is the solicitation of customers or, as in the case of Ms A, a means of attention getting would be hard to determine without specific knowledge of needs, wishes, and fantasies. Some combination of motives is likely. It would be reasonable to imagine that many of the denizens of such red-light districts would have personality structures and dynamics quite like those of Ms A.

An important issue is whether or not Ms A is indeed a genital exhibitionist rather than a body exhibitionist. Since she exhibits breasts and genitals and is essentially naked except for her raincoat, it is assumed that when she flashes she reveals most of her nakedness. Even if it could be assumed that what is most important to Ms A, in fact or fantasy, is that she exhibits her genitals, would her case still be properly classified as a sexual deviation? Certain criteria have to be met to distinguish exhibitionism as a sexual deviation from exhibitionism in the broader sense. The definition of exhibitionism used by the authors is taken from the subsection entitled "Perversion" in *Comprehensive Textbook of Psychiatry* (1). In the opening paragraph of this subsection it is stated, "Perversions are manifestly sexual in character. When the pathological impulses are released orgasm is achieved." Stoller states as part of his definition of perversion that it is an "habitual preferred aberration necessary for one's full satisfaction" (2). Ostrow and associates describe perversion as "an erotic technique" that one uses as a "complete sexual act" (3). Their definition requires that the behavior "leads to orgastic discharge." The typical exhibitionist exposes himself for sexual gratification, usually reaching orgasm through masturbation (4).

The case of Ms A appears to be neither unique nor a case of genital exhibitionism as it is usually defined. Her behavior does not sexually excite or gratify her. It is rather the regressive behavior, under the influence of alcohol, of an immature woman with intense body narcissism. The case does not seem to contribute much to the understanding of sexual deviation, despite the implications of the title and the overall manner of presentation.

MILTON EBER, PH.D.
Miami, Fla.

Dr. Hollender and Associates Reply

SIR: Dr. Eber's disagreement with our paper is essentially based on the definition of genital exhibitionism, which we define as the deliberate exposure of sex organs under inappropriate conditions for the purpose of evoking a response in an observer. Such a definition permits the inclusion of the act as an attention-getting maneuver as well as the expression of castration anxiety. In Dr. Eber's definition, sexual gratification and orgasm are emphasized, thereby excluding acts based on pregenital needs.

We agree with Dr. Eber's contention that the phenomenon we described is "the regressive behavior . . . of an immature woman with intense body narcissism" and suspect that such a description might fit other women who are genital exhibitionists.

Blood Types and Affective Disorders

SIR: Robert W. Shapiro, M.D., and associates reported in "ABO Blood Groups in Unipolar and Bipolar Manic-Depressive Patients" (February 1977 issue) that "A significantly higher percentage of bipolar patients than unipolar patients had blood group O, while a significantly higher percentage of unipolar than bipolar patients had blood group B." The authors assert quite reasonably that this finding supports the validity of the unipolar-bipolar distinction. Their further view that vulnerability to manic-depressive disorders may be related to membrane disturbances may be correct, but is not necessarily related to the implications of their report. Flemenbaum and Larsen (1) reviewed this topic and have shown some of the sources of error in the handling of statistics, but it is not on such grounds that Shapiro and associates' concept must be questioned.

If, indeed, there is a distinction in the frequencies of the O and A blood groups in manic-depressives as compared with the general population (as is shown in the table in Shapiro and associates' article), it would imply a locus on chromosome 9 for at least one genetic factor in these psychoses (2). One would then expect to find a familial pattern of inheritance relating the two phenomena. Such a pattern is seen, for example, in the nail-patella syndrome. This is instructive, for as Renwick and Lawler (3) showed, when a sufficiently

large number of families are studied the ABO frequencies do not differ from those of the general population. However, *within* families the inheritance of the syndrome occurs strictly in accordance with the blood type of the "founding" ancestor. Exceptions occur only as a result of recombination, at the rate of about 5%.

If, as seems likely, manic-depressive psychoses have existed in human populations for untold generations, there should not be a distinct difference in the ABO groups between the general population and the manic-depressives. We might consider a simple possible explanation for the data of Shapiro and associates: One "founding" ancestor, perhaps a manic with high political or military power, had blood type O, and through multiple matings in Denmark with OO, AO, BO females would have about a 66% chance of having OO progeny.

The proper way to examine this matter is through studies of families, but this is somewhat difficult. In the last two years, in the course of family studies, I have been able to examine only three families of individuals with bipolar affective disorders having afflicted members in at least two generations and with a sufficient number of cooperative relatives that such a relationship might be sought. In one family the data are not informative, but in the other two there is no segregation of blood type with clinical trait or state. Of course, such negative data are very slight and stand to be contraverted by positive family occurrences.

WILLIAM J. TURNER, M.D.
Central Islip, N.Y.

Dr. Shapiro and Associates Reply

SIR: Dr. Turner states that there should not be a distinct difference between the frequencies of ABO blood groups in the general population and in manic-depressive patients if manic-depressive illness has existed in human populations for untold generations. This statement applies only if one considers the relationship between manic-depressive disorder and ABO blood groups to be one of linkage. However, this statement does not apply if the relationship is one of casual association. Dr. Turner's example of the nail-patella syndrome suggests that he is thinking only in terms of linkage. The relationship between the nail-patella syndrome and the ABO blood group system is due to autosomal linkage, and this condition is not associated with ABO blood groups in unrelated patients. Our own observation of a higher frequency of blood group O in bipolar patients is probably more analogous to the well-known association between blood group O and duodenal ulcer. As Penrose (1) has pointed out, this association may be due to an effect of the O gene itself, rather than to that of an ABO-linked gene. Similarly, our own observation could be the result of an effect of the O gene itself.

Finally, we cannot entirely exclude the possibility of the "founder" effect hypothesized by Dr. Turner, although we find it rather unlikely, since the Danish population is very outbred and probably without detectable stratification.

Ethics and Health Policy, *edited by Robert M. Veatch and Roy Branson. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 324 pp., $15.00.*

The Institute of Society, Ethics and the Life Sciences, which published a highly regarded volume on the teaching of medical ethics, has established a research group on ethics and health policy. This book is the result of that effort. The tone set by the editors disavows simplistic solutions and clarifies differences among experts, giving the reader a much more realistic picture of the complexity of ethical issues as they relate to general medical practice, including psychiatry.

The book is divided into three sections. The first, Health Care Delivery: Fundamental Ethical Conflicts, presents a broad conceptual framework for examining the ethical implications of patient care in the social context. Leading scholars in the fields of philosophical and social ethics address and debate issues such as the right to health care. Also included in this section is a fascinating chapter on medicine in China. The second section, Ethics and Allocating Scarce Medical Resources, examines some of the moral dilemmas associated with advanced medical technology (e.g., the artificial heart). Section three, Ethics and Health Policy Planning, elucidates such issues as measuring economic benefits of health programs, community participation in health care decisions, technology assessment, and genetics.

The general level of scholarship in this book is excellent. Despite the theoretical excursions into philosophical and social ethics unfamiliar to most physicians, it reads extremely well. I found it refreshing that conflicting opinions and debate are highlighted.

Psychiatry and medicine cannot afford to ignore the issues raised in this book. However, theories of philosophical and social ethics and the theories found in the psychiatric field (developmental psychology, psychoanalytic theory, social systems theory, group dynamics, and knowledge regarding institutional behavior) that need to be brought together have not been in this book. Also, this particular volume lacks a sufficient psychological perspective. Such a perspective is generic to the study of individual and social ethics, which are unavoidably and profoundly psychological. The lack of a psychodynamic perspective gives a sense of one-dimensionality to the book's otherwise excellent content.

Not only this volume but a number of others written by philosophers, theologians, and social scientists on the subject of medical ethics tend to focus on exotic moral and ethical problems, e.g., when to prolong life, the feasibility of artificial hearts, and the control of genetic abnormalities. I believe it is much easier to debate these topics than it is to address the everyday nitty-gritty issues of moral conduct and rectitude that take place between physicians and patients. This point is especially important for the psychiatrist. Such issues extend beyond the one-to-one patient-therapist relationship. In dealing with patients the psychiatrist invariably deals with individuals who are related to other people in a social context—spouses, children, parents, and friends.

I feel that this book correctly links ethical principles of medical practice with issues of social justice. Despite minor shortcomings, the book is an important beginning. The intent of the editors is obviously directed toward interdisciplinary collaborative work. Physicians and psychiatrists are challenged to face squarely both matters that have to do with their own moral rectitude in behavior with patients (individual ethics) and their responsibilities to the community at large (social ethics). As Ortega said, "I am myself and my circumstance"; this includes the social context. In other words, psychiatrists and physicians must attend to the ethical problems arising in their relationships to their patients as well as to the system of care of which they and their patients are a part. Anything less is an abrogation of professional responsibility.

Psychiatric Education: Prologue to the 1980's: Report of the Conference on Education of Psychiatrists, Lake of the Ozarks, Missouri, June 9–15, 1975, *by Anne H. Rosenfeld. Washington, D.C., American Psychiatric Association, 1976, 512 pp., $15.00.*

The Working Papers of the 1975 Conference on Education of Psychiatrists. *Washington, D.C., American Psychiatric Association, 1976, 423 pp., $12.50 (paper).*

Psychiatric Education is a report of a conference that was held at the suggestion of the APA's Council on Medical Education and Career Development and APA's Committee on Medical Education. The council and the committee felt that in the last 10 years important social, economic, and political changes have taken place that profoundly affect the delivery of health care services, including mental health care services. They also felt that these changes would have important implications for the education of future psychiatrists.

When the conference was planned in the 1960s, there was a great deal of violence in our society—a struggle for civil rights, the demand for medical care for the poor, and demonstrations for an end to the Viet Nam conflict, for example. During this time, as a response to specific troubled areas, the Civil Rights Act was passed, Medicare and Medicaid developed, community mental health centers were built, and efforts were made to shorten medical school education and residency training.

By the time the conference was held in 1975, after Viet Nam and Watergate, there was a strong distrust of government, leadership, and authority. Through consumer groups and through Congress the public was demanding accountability, reflected in government attempts to control the cost and quality of medical service. At the same time, the federal government was reducing the funds spent for education of psychiatrists. Because the demand for mental health care is constantly changing and the form that the mental health sys-

tem will take in the 1980s is yet to be determined, the conference could deal with only general goals and general principles of education.

Psychiatric Education is based on the reports of seven preparatory commissions, reactions to each of these reports, propositional reports of 12 workshops, and proceedings of the conference plenary session. The following topics were discussed: goals and values, the resident (the student), faculty, educational methods, the environment, the economics of training, the social context of training, and evaluation of competency and quality control. Data are presented in each chapter to support the statements made. When such data were not available, normative views of very distinguished educators are supplied.

Unfortunately, very limited funds have been invested in research to investigate in depth the process of education for psychiatric residents. Such research might answer many of our questions. Some of the areas that need to be investigated might include the questions of what factors facilitate or impede the education of residents and what is the relative contribution to the process of education of faculty, students, educational methodology, and environment.

If there was one single focus in this conference it was evaluation and quality control. There was a general consensus that efforts must be made to measure the effectiveness of the educational process and the competency of the graduate. Knowledge is relatively easy to measure; skills and values are far more difficult to evaluate.

From this conference came a clear set of guidelines designed to enhance the broad knowledge of psychiatrists. A modification of these guidelines has already been published by the Residency Review Committee of Psychiatry and Neurology. These guidelines will be subjected to quality control and accountability by both the medical community and the public at large.

Anne Rosenfeld has captured the spirit of the conference very effectively. Her book can be recommended to any educator who is seriously interested in the education of psychiatric residents. Many educational principles found in *Psychiatric Education* could be applied to the education of medical students and child psychiatrists.

BERNARD HOLLAND, M.D.
Atlanta, Ga.

Maturation of the Therapeutic Community: An Organic Approach to Health and Mental Health, *by Maxwell Jones, M.D. New York, N.Y., Human Sciences Press (Behavioral Publications), 1976, 163 pp., $12.95.*

In this work Maxwell Jones has brought together in one brief volume many cogent observations from his almost 30 years of work with a variety of organizational systems. His purpose is to describe how a social systems approach can be useful in understanding interactional processes, how movement toward a more open social system can be beneficial to the society as a whole, and, specifically, how the open systems approach can enhance the functioning of a variety of mental health settings.

After a somewhat confusing and not well-focused foreword and introduction, the book moves rapidly to its major theme as Jones begins to show how a relatively static system can gain momentum toward openness and change through specific interactional methods. His descriptions of the preliminary or team-building phase, the process or action phase, and the evaluative or evolutionary phase are well written. They clearly outline and discuss principles that are valuable to any worker, professional or nonprofessional, in a mental health system. These processes are certain to be familiar to anyone who has worked in a mental health system, whether it be a hospital, community mental health center, or academic department of psychiatry. Jones also provides informative anecdotal material based on his personal experiences as a facilitator and/or interventionist in each of these three settings; these anecdotes help to illustrate his theses.

Jones only briefly examines the specific relevance of his theoretical positions for the practice of psychiatry; he raises more questions for me than he answers. However, it is clear from this book that the different organizational settings in which a psychiatrist chooses to practice may require different role orientations. The independent private practitioner rarely needs to be concerned with his or her role in a system, although this may change as peer review, Professional Standards Review Organizations (PSROs), and national health insurance become more prominent influences. In contrast, the psychiatrist who works within a system often has many problems in defining his or her role in relationship to the system and the other people in it. I believe this difference raises some important issues for training programs, specifically involving the mechanisms by which they prepare or fail to prepare psychiatric residents for work in a mental health system. For example, is it possible that some of the concern raised about the role of psychiatrists within some community mental health centers is related to the failure of training programs to adequately prepare the psychiatrist for participation in an open system? This question and others related to the role of the psychiatrist receive relatively little attention in *Maturation of the Therapeutic Community*.

Although Jones stresses the importance of evaluating the effectiveness of an open system as it affects therapeutic outcome, he does not discuss one of the most important consequences of the open systems approach, namely the recent emphasis on patients' rights. One must wonder whether this would have become as prominent an issue if it had not been antedated by the move toward an open systems approach in many mental health settings. A thorough examination of the open systems approach and its legal derivatives is needed, particularly as this relationship affects the quality of treatment and treatment outcome.

In summary, this book brings together many of Maxwell Jones's theories and precepts regarding organizational development as it pertains to mental health systems. For psychiatrists who work within one of these systems, an understanding of these principles is most relevant to their work.

ALLAN BEIGEL, M.D.
Tucson, Ariz.

Caring, *by Willard Gaylin, M.D. New York, N.Y., Alfred A. Knopf, 1976, 199 pp., $7.95.*

Dr. Willard Gaylin is a psychoanalyst, a professor of psychiatry, and president of the influential Institute of Society, Ethics and the Life Sciences. For many years and through a series of books, he has devoted his professional expertise to the cause of social justice. In *Caring*, he argues passionately that man is now in a crisis of self-confidence, increasingly convinced of his innate destructiveness and losing hope for his future.

Dr. Gaylin believes that this problem has been engen-

dered, at least in part, by the scientific errors of psychoanalysis and ethology that have one-sidedly focused on the hostile, destructive, selfish tendencies of our species. To surmount the gathering crisis of despair, Dr. Gaylin urges on us a corrected view of human nature:

> If there is one fact founded in his biology, essential to his survival and uniquely his own, it is that *Homo sapiens* is supremely a loving animal and a caring one. . . . I do not deny that there may be a genetic directive for aggression in mankind, but the genetic basis for love is far more obvious, and that is what I plan to explore here. (pp. 10–11)

To prove this thesis, Dr. Gaylin reviews newer researches in ethology, mother-infant interaction, psychoanalytic developmental theory, and object relations theory. Chapters on attachment, separation, identification, and conscience provide a fascinating new look at the relevant data in these vital areas of psychic development. The author's emphasis is on the ways in which dependency, tender emotions, loving care, and socially cooperative behaviors play a central role in the formation of human beings in human society. The case is convincing.

As a friendly critic of psychoanalysis, Dr. Gaylin discusses the historical reasons for the delay in achieving an appropriate balance in the psychoanalytic view of man. In "Totem and Taboo" (1), one of his early works, Freud recognized the need to root conscience and group cooperation in the evolutionary history of mankind—i.e., in man's genetic structure. However, as psychoanalysis became increasingly preoccupied with the nature of drive theory, and because "Totem and Taboo" seemed hopelessly Lamarckian in outlook, this early insight was lost. "Civilization and Its Discontents" (2), with its dramatic opposition of the self and society, became the standard of psychoanalytic sociology. Today's cultural climate, concerned with pollution, overpopulation, and nuclear warfare, is beginning to shift scientific interest from man's capacity for conquest to his capacity for cooperative survival. *Caring* is clearly one of a number of works in social biology that have begun to emphasize the constructive social capacities of the species.

Dr. Gaylin contends that man essentially designs himself. The social structure of a society, particularly the kind of mother-child interactions that each culture encourages, determines the nature of the child. Hope and self-confidence are necessary to encourage loving interactions and produce loving progeny:

> I do not despair at the state of the world; I despair at the current state of passive disenchantment and self-denigration. Given knowledge of the nature of the human being, such worry is warranted. And psychological definitions of the human state tend to be self-fulfilling prophecies. We may not be what we think we are—but what we think we are will determine in great part what we are to become. We must not design our future in terms of our disillusionment with self, for those designs, even if erroneously conceived, will influence the future development of our species. (pp. 170–171)

Although Dr. Gaylin conveys a sense of crisis, he is in fact a thoroughgoing optimist. His writing is dramatic, which may not be to everyone's taste, but he is bursting with ideas and interesting asides, and he manages to present masses of data with zest and enthusiasm. The scholarship is excellent, and the book is a valuable presentation of a newer point of view in the science of human behavior. *Caring* will be of interest as a review of the literature and as a source of new ideas for students and professionals. It can be understood by the intelligent nonprofessional reader as well. The footnotes and bibliography are excellent and are presented in a form that is a model for scholarly work.

Mysticism: Spiritual Quest or Psychic Disorder? Report 97, *by the Group for the Advancement of Psychiatry Committee on Psychiatry and Religion. New York, N.Y., GAP, 1976, 110 pp., $4.00 (paper).*

Many features of the mystical experience have remained puzzling to Western students of human nature on many counts, including its psychodynamics; its relation, if any, to psychosis; and its validity as a revelation of features of the universe inaccessible to waking consciousness. The growing popularity of mystical cults in the United States has created a new interest in these questions, and this admirable brief report represents the efforts of a group of psychoanalytically oriented psychiatrists to come to grips with them.

After describing the mystical experience and surveying the current mystical scene in the United States, the report goes on to an overview of Jewish and Christian mysticism, followed by thumbnail biographies of three widely different mystics in three cultures: Ramakrishna, Jacob Frank, and Ignatius Loyola. On the basis of these descriptions, the authors explore some possible psychodynamic sources of the mystical experience and its relation to psychoses and creativity. The biographies make it clear that mystical experiences are not confined to any one type of personality. Ramakrishna was emotionally unstable, suffered from psychotic-like episodes, and went into spontaneous trances; Jacob Frank was a charismatic person openly pursuing wealth and power; and Loyola was a hard-driving, obsessional ascetic.

The authors of the report conceptualize mystical trances as efforts to cope with an unacceptable outer reality by turning away from it to a gratifying inner one characterized by self-absorption and often a consoling reunion with symbolic representations of parents. Consistent with the authors' psychoanalytical orientation, these features are analogized to regression to an infantile state, which differs from psychotic regression in that it is facultative rather than obligatory, partial rather than complete, and compatible with forming close bonds with others rather than isolating. The authors have shown praiseworthy self-discipline in confining more adventurous psychoanalytic speculations to a brief epilogue.

When all is said and done, essential features of the mystical experience remain inexplicable in terms of Western cosmology. This report wisely confines itself to a consideration of features that can be empirically studied and offers much fascinating information, objectively presented and thoughtfully

discussed. It can be highly recommended as an introduction to the psychology of mysticism.

JEROME D. FRANK, M.D.
Baltimore, Md.

Annual Progress in Child Psychiatry and Child Development 1976, *edited by Stella Chess, M.D., and Alexander Thomas, M.D. New York, N.Y., Brunner/Mazel, 1977, 744 pp., $17.50.*

For nine years the editors of this review have displayed a remarkable catholicity in assembling material related to the field of child development, the practice of child psychiatry, and the concerns of professionals and others about children. Developmental issues and theories have been a major concern of the editors; this is reflected in the selection of material from a series of serious and learned theorists.

As the editors have noted before and repeat in this year's *Annual Progress*, much of the material written on developmental issues tends to be speculation. They therefore include as a lead article a paper by Sameroff titled "Early Influences on Development: Fact or Fancy?" I agree with the editors that this article is a true milestone. It sets up a transactional model that emphasizes continuity and discontinuity in the developmental process of a child. It emphasizes the relationship of a child's progress to his or her environment in a systematic way that has only been suggested before. It may well warrent being labeled a classic.

In the 1975 *Annual Progress* the heading Social Issues and Public Policy appeared for the first time. There are no papers grouped under this topic in the present volume, but it appears to me that a host of articles could have appropriately fallen under that rubric. The appearance of such a large number of articles devoted to the concerns of society as well as clinical concerns sets a new tone for this particular volume.

The section on Racial Issues of the previous volumes has become Minority Issues. An outstanding paper by Gordon, "New Perspectives on Old Ideas in Education for the Minority Poor" as well as one by Robins and associates on "Arrests and Delinquency in Two Generations: A Study of Black Urban Families and Their Children" highlight this section. The former points out clearly what has and what has not happened in the educational efforts that have been made. The latter once more illustrates how difficult it is to move individuals out of a delinquent rut once the family is cast in that mold.

To continue the concerns about social issues, an entire section focuses on child abuse. Sibylle Escalona, in "Children in a Warring World," provides the opening for this series of articles, which continues with papers on drug abuse, professional abuse, and adolescent violence. It was difficult to choose the outstanding article in this group because so many of them are good. I feel, however, that one should not overlook King's paper on "The Ego and the Integration of Violence in Homicidal Youth" or Polier's calm and considered essay on "Professional Abuse of Children: Responsibility for the Delivery of Services."

One of the neglected areas in child psychiatry over the years has been that of the relationship of siblings and the influence of siblings on the development of an individual. To fill this vacuum the editors have chosen Bank and Kahn's outstanding paper "Sisterhood-Brotherhood Is Powerful." It leads off a section on the family that is complemented by a paper by Rosenthal and associates on "Parent-Child Relationships in Psychopathological Disorder in the Child." Using Minuchin's now familiar interest in the family, Minuchin and associates contribute a well-ordered clinical paper, "A Conceptual Model of Psychosomatic Illness in Children."

I have alternately despaired and exulted at the selection of papers in this series. This volume leads to a sense of joy once more. The joy is in the writing and the description (not, certainly, the reality) of the difficulties that society is having in handling problems of children. Akin to the description of society's failures outlined by Steiner in *The Children's Cause* (1), several of the articles mentioned above, and others, emphasize the fact that we understand many of the problems of children but lack an understanding of the pathology of the process by which we care for children.

It does appear, however, that the field of child psychiatry is producing something; that larger social problems are a concern of the field; and that we are looking at the relationship of issues derived from the field of psychiatry that have wide and concerned implications. If we were able to see as clearly the clinical process implicit in the methods by which we legislate and try to organize services for children, we might begin to make better progress in the whole field of child care.

Double Bind: The Foundation of the Communicational Approach to the Family, *edited by Carlos E. Sluzki, M.D., and Donald C. Ransom, Ph.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1976, 347 pp., $19.75.*

When I was a medical student, the first paper on the double bind theory, "Toward a Theory of Schizophrenia" by Gregory Bateson, Don Jackson, Jay Haley, and John Weakland (1, pp. 201–227), created a great stir of debate in the psychiatric faculty. It appeared to be an idea that at once explained why schizophrenic patients were not only disturbed but had a defect in their thinking, what that defect might have to do with the communication process of the family, and how all that might be related to humor, hypnotism, psychotherapy, cybernetics, and linguistics. In other words, it was a Breakthrough. Twenty years later, the excitement has still not died down. The theory has been extended and clarified by the original authors and by their students and critics.

In *Double Bind*, Carlos Sluzki and Donald Ransom have brought together the essential original papers, 17 in all, and several chapters of commentary. Aside from the commentary, 6 of the pieces appear in print for the first time. The whole is arranged to convey the history of the development of an idea. Indeed, one of the most valuable new contributions is Haley's history of the project itself, with Bateson's and Weakland's comments on it.

This book is a scientific adventure; let me say at once that I recommend it to historians of science as well as to clinicians and researchers in the mental health field. It is also a monument to the extraordinary influence of Gregory Bateson. Those who found it difficult to get the message of his *Steps to an Ecology of Mind* (1) may find him better delin-

eated here as he and his colleagues debate with each other. Reading the debate, one realizes that we have learned from them the language and metaphors of communication theory; and no matter what we think, the way we think will never be the same.

The commentaries point out, repeatedly, that the project was not exclusively or even primarily interested in schizophrenia. Indeed, according to Haley's history, the project began with the study of communication patterns in small groups of humans and animals engaged in such activities as play and psychotherapy. They decided to concentrate on schizophrenia when their Rockefeller grant ran out and a more practical project had to be funded. By the end of the project (10 years later), each of the original group had turned to other concerns (hypnosis, psychotherapy, general family therapy, dolphins), but for academic psychiatry, an etiology of schizophrenia had been proposed and had to be tested. People started defining and counting double binds in family interactions. This research is masterfully reviewed here by Gina Abeles, a sociologist at Boston University, who concludes that whenever the concept was operationalized something essential to it seemed to have slipped away. This is because it is not an etiological agent but a language of description that is especially apt for schizophrenia in its family context but good for other situations as well. Like any language, it loses a great deal in the experimental translation from its natural context. This, the editors say in their commentary, is the whole point: the idea is not for testing, it is for thinking. In the rest of the book they collect very elegant examples of this idea.

Alan Watts, Jules Henry, Paul Watzlawick, Morton Schatzman, and Ronald Laing are all represented by fragments that show them at their best; clearly the double bind has taken each of them around an important corner in his explorations. Lyman Wynne presents a very moving article titled "On the Anguish, and Creative Passions, of Not Escaping Double Binds." It is an important piece for therapists.

I found a few disappointments: in his article on the clinical use of the concept Richard Rabkin begins by applying useful criticism to the separate definitions of paradox and double bind, but he promises us a new science of the double bind correctly defined and distinguished and does not deliver. Anthony Wilden and Tim Wilson have a think-tank piece about logic, magic, and economics that in telegraphic terms relates everything to everything else on a breathtaking level of generality that I have not seen since college term-paper days. Their conclusion is that we should prefer cooperation to competition, but if I were not convinced of that to start with I do not think this kind of intellectual tour de force would change my mind.

One piece especially exemplifies what the book is about. Carlos Sluzki and Eliseo Veron in "The Double Bind as a Universal Pathogenic Situation" apply the concept to the genesis of hysteria, phobia, and obsession, taking Fairbairn and learning theory as their point of departure. This shows in action how the double bind concept is useful: it is a general way of thinking about duplicity and unawareness in social systems. As such it has much the same function as the idea of the unconscious in Freudian psychoanalysis.

There is another interesting similarity between the Bateson group and Freud. Both turned aside from their development of a general theory to deal with schizophrenia as a special case. Freud's detour, the analysis of the Schreber case, has caused as much commotion, exegesis, and debate as has the double bind and for the same reason. The etiology of schizophrenia is the Great Prize in the quest of academic psychiatry, a company from which Freud was as removed in his day as was the Bateson group in the early 1950s. Both Freud and the Bateson group made presumptuous and provocative statements on the occasion of their entering the schizophrenia debate from the outside. Now that official psychiatry has accepted them as prophets in their own right, we should not go back and argue their diminishing claims to the etiology of schizophrenia. They have changed the way psychiatrists think about civilization and human relationships, and they—here I think particularly of Haley and Jackson in the Bateson group—have contributed immeasurably to the art and craft of psychotherapy.

This book defines the Bateson group's scientific position in multiple perspectives. It should not be read only for its contribution to the problem of schizophrenia or even the problem of communication and the family. As Weakland says in his final comment, the original paper was not so much a report as a command—to look at things differently. As such, it has put us all in a lasting and therapeutic bind.

C. CHRISTIAN BEELS, M.D.
New York, N.Y.

The Hospitalized Adolescent: A Guide to Managing the Ill and Injured Youth, *by Adele D. Hofmann, R.D. Becker, and H. Paul Gabriel. New York, N.Y., Free Press (Macmillan Publishing Co.), 1976, 243 pp., $14.95.*

We always seem to be subdividing, specializing, subspecializing—even superspecializing. First there was medicine; then came a cloning into internal medicine and pediatric medicine, then psychiatric medicine and child psychiatry, down to two different limbs, liaison psychiatry and adolescent psychiatry. Must we forever divide, subdivide, and discriminate so discreetly? My conclusion is yes, assuming that proper attention is related to the whole. There is value in specifically focused knowledge and skills, along with a hazard or two.

The Hospitalized Adolescent is truly an important, good book. It is a special book for nonpsychiatric physicians who hospitalize adolescents for medical and surgical problems as well as a good book for those in child, adolescent, or liaison psychiatry who may consult on matters of psychological management of the hospitalized adolescent. The book evolves into a beautiful reweaving of adolescent medicine, psychiatry, and consultation and pulls them all together into a compassionate and knowledgeable statement on caring for the hospitalized adolescent with nonpsychiatric illness.

The book seems to me to be invaluable for every concerned professional dealing with the hospitalized adolescent. Aside from being an excellent primer for teaching purposes, it would be useful for our nonpsychiatric colleagues to read this thoroughly sensitive, well-balanced book. The volume's organization, the clearly labeled selected bibliography at the end of the book, and the detailed case histories woven throughout the text are all handled in an excellent manner. Topics covered include the critical issues of "normal" adolescence; ward interactions among patient, nurse, physician,

and other caretakers; direct patient care advice; a discussion of common behavioral problems; and the neurological, orthopedic, and psychological consequences that present unique problems for the adolescent.

The major reason for urging this book's dissemination among our medical, nursing, and allied professional colleagues is summarized best by Anna Freud's foreword:

> Illness in adolescence, as described by the authors, negates the very progression toward independent adult status which is the aim of this developmental stage. It threatens self-management of bodily functions, freedom from control by external authority; dashes hopes of winning athletic renown or attracting the other sex. No wonder that under these conditions the ill adolescent revolts—against medical or surgical interference which, to him, seems to aggravate matters, not relieve them; against nursing care which seems to return him to the infantile situation of having his body owned and handled by the adults; and against hospital rules which disregard his new need for self-determination. There exists, apparently, no easy way out of this impasse: it is either revolt or utter resignation, depression, and passivity.
>
> The authors of the book accomplish the almost incredible feat of viewing the whole turmoil not from the hospital's, the doctors', or the nurses' side, but from that of the adolescent patients themselves. They are confident that this is the method to circumvent the worst troubles; to allay irrational anxieties; to eliminate unnecessary aggravations; and to create, even in the face of these stressful circumstances, an atmosphere of trust, cooperation, and joint endeavor.

I know of no other resource which contains so much valuable, practical, and easily read information on the problems of the hospitalized adolescent or proposes such sensible preventions and solutions for those special problems.

Family Therapy: Theory and Practice, *edited by Philip J. Guerin, Jr., M.D. New York, N.Y., Gardner Press (Halsted Press, John Wiley & Sons, distributor), 1976, 547 pp., $24.50.*

A.D. 2001 is not where family therapy is yet, and neither is this book. I question how many books on this topic we need; I own at least 20. This one is current and perhaps 5% ahead of last year's crop. There are 29 contributors and 31 chapters. Nine chapters are written by Murray Bowen or by his students Philip Guerin and Thomas Fogarty.

The book contains many historical and factual inaccuracies (see, for example, the section about the origins of family therapy in Philadelphia, pp. 10, 11). The chapter references have not been standardized, and I spotted several reference errors. However, this book will be valuable to younger family therapists; it is an up-to-date collection of views and practices by a variety of family therapists.

Murray Bowen explains and expands his family systems theory—the I-position, the differentiation of self scale, triangles, the family projection process by which parental undifferentiation impairs one or more of the children, emotional cutoff (a way people handle their unresolved emotional attachments to their parents), and the multigenerational transmission process ("If we follow the most impaired child through successive generations, we will see one line of descent producing individuals with lower and lower levels of differentiation"). Bowen now feels it may take 8 to 10 generations to produce the impairment seen in a schizophrenic person. Other elements of the Bowen theory include the importance of sibling position and his newer concept of societal regression. By his own admission (p. 89), Bowen's theory is not understood by many professionals. Many of his concepts appear to me to be elaborations of the earlier ideas of Harry Stack Sullivan.

John Weakland develops the cybernetic or systems approach to family interaction. Central to this theory is the following: "1) that specific behavior of all kinds is primarily an outcome or function of communicative interaction within a social system; and 2) that 'problems' consist of persisting undesired behavior."

Most of the authors subscribe to a systems model of family therapy, but the personal applications vary greatly. Innovative chapters by Carolyn Attneave, Norman Paul, Lynn Hoffman, Peggy Papp, Peter Laqueur, and others are worth reading. Several chapters focus attention on techniques with children.

This is a book for clinicians. It would probably be best read by sampling a chapter here or there (which I did on my second reading). It compares very favorably to other family therapy texts.

Carl Whitaker's chapter, "The Hindrance of Theory in Clinical Work," will be a remembered classic. I think it is a highlight of this book, dazzling in the professional skill, humor, humanity, and wisdom of its author: "I have a theory that theories are destructive. . . . Look. It's worse than you think. And if you think it's much worse."

On the Origin of Schizophrenic Psychoses: Symposia Organized by the Interdisciplinary Society of Biological Psychiatry, *edited by H.M. van Praag. Amsterdam, The Netherlands, De Erven Bohn BV, 1975, 222 pp., $18.00 (paper).*

This is a book worth having by any standard, and it will be particularly valuable to most readers of this journal. Edited volumes are, in general, abominations. Some are collections of pieces that edited journals have rejected, and others are proceedings of conferences that took place many years in the past. This volume is of neither sort: it covers two congresses in Amsterdam of the Interdisciplinary Society of Biological Psychiatry held in September 1974 and January 1975. Even with such prompt publication, if this had been a conference in the United States the important contributions would have appeared by now as journal articles in publications generally read by the average American psychiatrist. In this volume, Seymour Kety is the only American contributor, and his sayings wear well with time anyway. The rest of the contributors are European, principally Danish, Dutch, and British, and they provide a remarkably broad and balanced survey of the ways Europeans attack the problem of schizophrenia. Many of these authors appear rarely or not at all in the more popular American psychiatric journals.

Like all symposium reports, the papers are uneven; some have obviously not been reviewed by an editor whose first language is English. However, all are interesting and some are brilliant. Topics range from neurochemistry to psycho-

analysis. Perhaps we have the Dutch tradition of intellectual tolerance to thank for such a refreshingly ecumenical volume, in which Sedwick's commentary on Laing and Cooper can repose cheek by jowl next to Hirsch's paper demonstrating beneficial effects from depot fluphenazine.

Because the volume contains 15 different papers, only a few can be singled out for special comment; this selection is by necessity largely a matter of personal taste. H.M. van Praag is well known to American psychiatrists; his contributions live up to what we have come to expect. I also found Hutt's "An Ethological Analysis of Autistic Behavior" particularly exceptional. The connection he makes between stereotypies and hyperarousal seems neatly defended. I realize now that I should have been more familiar with Hutt's work, but it does not appear regularly in the journals I keep up with. I mention this to illustrate how this volume has brought me in contact with work that my parochial habits have led me to neglect. I suspect other American psychiatrists will find this volume equally useful for similar reasons.

ENOCH CALLAWAY, M.D.
San Francisco, Calif.

Behavior and Brain Electrical Activity, *edited by Neil Burch and H.L. Altshuler. New York, N.Y., Plenum Publishing Corp., 1975, 555 pp., $32.50.*

This volume is the result of a symposium dealing with hard quantitative measurement of brain electrical activity. The first portion of the book deals primarily with electroencephalographic measurement of sleep profiles and their relationship to basic endocrine function. The change in electrical activity of the brain as a function of drug effects, biofeedback, and external electrical fields is also considered in a series of contributions. The final section of the volume is concerned with the behavioral patterns of violence and aggression.

The editors attempt to organize the large number of contributions into a meaningful volume in five sections. These include Sleep Profiles and Behavior, Measurement and Analysis of Electrical Activity, Change of State (particularly as induced by drugs and feedback effects), Maturation and Pathology, and Violence and Aggression. There is no question that this volume represents a major review of the important quantitative techniques for analyzing brain electrical activity in relationship to a number of important aspects of human and animal behavior. The contributors include well known and outstanding investigators.

Behavior and Brain Electrical Activity is a useful reference source for students and workers in this important interdisciplinary area of the neurosciences. This volume is recommended for all medical libraries as well as for researchers specifically interested in brain electrical activity, its quantitative measurement, and its relationship to behavior.

Ann Arbor, Mich.

Acute Drug Abuse Emergencies: A Treatment Manual, *edited by Peter G. Bourne, M.D. New York, N.Y., Academic Press (Harcourt Brace Jovanovich), 1976, 305 pp., $16.50.*

Once in a while a book appears that has potential for repeated editions. *Acute Drug Abuse Emergencies* could well become the equivalent of *Current Therapies* in the field of alcohol and drug abuse treatment. It is, in fact, a second edition, updating *A Treatment Manual for Acute Drug Abuse Emergencies*, which was published by the National Clearinghouse for Drug Abuse Information in 1974 with the encouragement of APA's Task Force on Drugs and Drug Abuse Education. Dr. Bourne did the original editing and organizing of the book while he was Assistant Director of the Special Action Office of Drug Abuse Prevention (SAODAP), long before he attained his current position of influence in the health care system.

The book is organized into 9 sections containing 28 chapters. The initial section on differential diagnosis is followed by sections dealing with opiates, CNS depressants, CNS stimulants, hallucinogens, marijuana, inhalants, alcohol, and special problems. The 41 contributing authors, 16 of whom are psychiatrists, represent a cross section of medical specialties.

The real strength of this book as a clinical reference is its index, which occupies 15% of the pages. Here are to be found useful references ranging from the use of pentylenetetrazol (Metrazol), picrotoxin, caffeine, and strychnine in treating alcoholic intoxication to the entry "zinc sulfate, never use as an emetic (p. 282)." The latter entry will get the reader involved in Eric Comstock's excellent chapter on "Chemotherapy for Drug Abuse Related Emergencies." Browsing through the index can provide informative fun as well as turning up such items as "complications of amphetamine use by athletes (p. 116)" and "psychiatrists more impressed with marihuana's dangers than academicians (p. 154)."

The most distracting aspect of the book is the variability in style and format used by the contributing authors. This variability is most evident in the references and in the organization of each chapter. Dole's chapter on "Management of the Opiate Abstinence Syndrome" has no references, while Glaser's chapter on "Inhalation Psychosis" and Victor's chapter on "Alcohol Intoxication and the Withdrawal Syndrome" each has 3 pages or more of references. Five chapters use the British reference style, which does not include article titles. My own preference is for the *American Journal of Psychiatry* reference style, which is more likely to stimulate me to look up a citation.

I hope that, in addition to exercising more editorial strength in future editions, Dr. Bourne can add some additional clinical material. A chapter on the management of acute medical complications of alcoholism would be useful. Included would be the alcohol-disulfiram (Antabuse) reaction, which unnecessarily frightens many physicians and limits the use of disulfiram as a valuable adjunct to the treatment of alcoholism. The management of neonatal alcohol withdrawal and other CNS depressant withdrawal would help physicians deal with the fetal alcohol syndrome and other newly recognized, related, and unfortunately common conditions. A specific chapter on the management of such behavioral problems as suicide, violence, manipulations, family turmoil, and child abuse might help clinicians feel more comfortable with alcohol- and drug-dependent patients who are often medically underserved as a result of these behaviors.

Acute Drug Abuse Emergencies can be useful for every branch of medical practice. It is of particular value to psychiatrists working in general hospitals, who may be called on by other physicians encountering alcohol or drug abuse problems. Dr. Bourne has made a good start toward the goal he presents in his preface, that of meeting "this largely unmet need in developing more generally disseminated expertise in

aiding the drug abuser." I hope he will continue his work with future editions.

JOHN N. CHAPPEL, M.D.
Reno, Nev.

Understanding EEG: An Introduction to Electroencephalography, *by Donald Scott. Philadelphia, Pa., J.B. Lippincott Co., 1976, 241 pp., $16.00.*

Clinical EEG reports on the charts of many psychiatric patients are frequently misunderstood by the physician who requested them. This is not surprising because the principles of this method are not adequately taught either at the undergraduate level or as a part of psychiatric residency training. Considering the cumulative price of many thousands of EEG records and reports, this is an expensive misunderstanding.

There are good EEG textbooks available, but these were designed primarily for the neurologist specializing in EEG or for the EEG technician. Dr. Scott has written an introductory textbook for the nonspecialist, drawing on his extensive experience with undergraduates and postgraduates at a busy EEG department of a teaching hospital in London.

The introductory chapters on recording technique and general description of normal and abnormal EEG are concise and easy to understand. The chapters on various disease states not only describe the EEG changes but clearly spell out the limitations of the method. False-positive and false-negative findings are discussed, and there is an unusual and very useful chapter titled "The EEG Report" that explains not only how to write one but also how to read one. A detailed and extensive glossary of EEG terms is appended.

Textbooks on EEG generally provide very little information on drug effects; this book is no exception. The EEGs of a majority of psychiatric patients are modified by psychoactive drugs; this complicates the clinical interpretation of the tracings. Additional information on EEG drug effects should be obtained elsewhere (for example, see Fink's essay[1]).

Scott's book is well written and easy to understand. It should be read by those who order EEG reports and expect to understand them.

Psychotherapy of the Borderline Adult: A Developmental Approach, *by James F. Masterson, M.D. New York, N.Y., Brunner/Mazel, 1976, 369 pp., $17.50.*

In this volume the author travels to the increasingly popular land of the borderline patient. He begins with a 2-chapter outline of an object relations theory of ego development. These are followed by 17 chapters containing reports of both supportive and reconstructive psychotherapy with borderline patients. The final chapter is a restatement of object relations theory with some reference to the many questions about ego organization that remain unanswered. The style is straightforward but repetitious, and there is a tendency in the theoretical sections to gloss over the complexities of conflicting hypotheses.

The author acknowledges his major debt in formulating his theory to Margaret Mahler. He also cites Kernberg at length and refers to Kohut's work. He does not, however, define the relationship between their theories and those of either the classicists or the ego psychologists. In consequence, the system Masterson presents is deceptively simple, as are the treatment approaches that spring from the theory.

By identifying confrontation as the principal technique of the initial phase of treatment, the author seems to encourage an earlier ventilation of aggression than most therapists would advise. It is true that a careful reading of the clinical sessions suggests that, perhaps intuitively, Masterson prepares the borderline patient for confrontational clarification with ego support and by bolstering adaptive responses to anxiety. The sections on theory give little attention to such techniques, however. Also missing from the discussion are criteria for treatability and for termination of therapy.

The achievements of the book are considerably more modest than its cost. Were it not for that deterrent, *Psychotherapy of the Borderline Adult* might be recommended to the novice as a relatively painless introduction to a broad and formidable subject.

ROBERT J. CAMPBELL, M.D.
New York, N.Y.

Empirical Studies of Alcoholism, *edited by Gerald Goldstein and Charles Neuringer. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 256 pp., $16.00.*

This monograph reviews some of the major topics in current psychological research in alcoholism. These include the use of psychological tests for the study of identification, prediction, and treatment; experimental investigations of tension reduction models; behavioral approaches to treatment; perceptual and cognitive deficit; neuropsychological studies of Korsakoff patients; typology of hospitalized alcoholic patients; and neuropsychological investigations.

Neuringer and Clopton review and critique the use of psychological tests for the study of the identification, prediction, and treatment of alcoholism. Included in their discussion are projective techniques (Rorschach, Thematic Apperception Test, Rosenzweig Picture Frustration Test, and Bender-Gestalt), psychometric personality tests, the MMPI (alcoholism scales, the prediction of future alcoholism, and response to treatment), and characteristics of alcoholic subjects identified by objective personality tests. Neuringer and Clopton conclude that, as yet, with the exception of the MMPI, these tests have been found to be of little value in diagnosing alcoholism.

Higgins examines the experimental investigations of tension reduction models of alcoholism, the problem in evaluating the tension reduction hypothesis, stress-induced drinking, and continued drinking in the face of aversive consequences. Following a careful evaluation, Higgins concludes that the specific role of tension reduction in the etiology of either normal or abusive drinking remains obscure.

Denney divides the behavioral approaches to the treatment of alcoholism into three categories: aversion conditioning (chemical, electrical, and verbal), operant procedures (contingent punishment and contingent reinforce-

ment), and broad-spectrum behavioral treatment. Denney views the shift from aversion conditioning to operant conditioning procedures as a fundamental change in treatment orientation and interprets the use of broad-spectrum behavioral treatment as indicating an acceptance of the multiple determinants influencing alcoholism. The following elements have been incorporated into the broad-spectrum treatment approach: specific measures for the physical rehabilitation of the patient; aversion conditioning to decrease the patient's urge to drink; relaxation, desensitization, and aversion training procedures seeking to eliminate the patient's social anxiety; alternative sources of reinforcement (e.g., hobbies and sports); and the enlistment of significant persons in the patient's environment for support. However, Denney emphasizes that this approach may at times be associated with a tendency to overlook the individual patient and rely on shotgun programs.

Goldstein reexamines the nature of the perceptual and cognitive deficit in alcoholic subjects, paying considerable attention to the concept of field dependence and field independence. Although this is a well-established observation, the explanation for this phenomenon is far from clear. One group of investigators view field dependence in alcoholic subjects as a predisposing factor present before acquisition of the alcohol addiction. However, others interpret this phenomenon as a manifestation of some specific consequence of alcoholism and/or situational variables that bear little relationship to the personality of the alcoholic subject or his or her cognitive style before becoming alcoholic.

Goldstein also reviews the alcoholic individual's ability to respond to a variety of testing procedures using different types of configurations and compares the temporal stability of performance levels. His findings suggest that alcoholism is associated with a series of partially reversible perceptual motor and cognitive deficits. He discusses their relation to the understanding of the alcoholic individual. Goldstein reports this characteristic among the more prominent descriptions making up a composite picture of the alcoholic patient who is most likely to drop out of treatment.

Butters and Cermak study the severe memory deficit of alcoholic Korsakoff patients. They center their attentions on the phenomena of anterograde amnesia from the standpoint of short-term memory, proactive interference, and encoding. Their evaluations indicate that Korsakoff patients are sensitive to proactive interference and that they are also deficient in the depth of their encoding. There also appears to be a general limitation in the amount of information Korsakoff patients are capable of processing in any given period of time as well as increasing evidence that Korsakoff patients have visuoperceptive impairments, an observation that suggests these patients may have an impairment in nonverbal memory that parallels their deficit in verbal analysis. Thus it appears that Korsakoff patients may have two separate neuropsychological syndromes: one characterized by anterograde amnesia, short-term memory deficits, and limitation in analysis of verbal materials; the other characterized by deficits on a number of perceptual tests that involve the analysis of complex unfamiliar visual stimuli. Other aspects of this matrix relate to motor memory and olfactory deficits and a comparison of the memory disorders of alcoholic Korsakoff patients, post-encephalitic patients, and patients with Huntington's disease.

Shelly and Goldstein present their findings on an objectively derived typology of hospitalized alcoholic patients. Surprisingly, this indicates that alcoholic patients who were employed immediately before hospitalization in an occupation with relatively high socioeconomic status and who performed in a normal range on the psychological tests were less likely to have a period of abstinence during the follow-up year than were other patients.

Tartar concludes the monograph with a summation of neuropsychological investigations of alcoholism. He finds that the impairment patterns of chronic alcoholic subjects is similar to that of persons suffering from acute brain damage. There is some discussion on the reversibility of the impairment, the rule of antecedent neuropsychological impairment, and the implications of these for treatment.

The 8 chapters are well documented by extensive bibliographies. The presentation is also enriched with 23 figures, 13 tables, and an author and subject index. For the student of alcoholism, the presentation is a scholarly assessment of the psychological progress made in the investigations of alcoholism in recent years. It can be recommended as a useful reference.

Further Studies of Drug Users, Treatment Typologies, and Assessment of Outcomes During Treatment in DARP. The Effectiveness of Drug Abuse Treatment, Vol. III, *edited by S.B. Sells and D. Dwayne Simpson. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 456 pp., $22.50.*

Evaluation of Treatment Outcomes for 1971–1972 DARP Admission Cohort. The Effectiveness of Drug Abuse Treatment, Vol. IV, *edited by S.B. Sells and D. Dwayne Simpson. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 476 pp., $22.50.*

In the first two volumes of what will be a five-volume series, Sells and Simpson and their coworkers analyzed data on 11,000 patients admitted to 23 federally supported drug treatment programs between June 1969 and June 1971. In volumes III and IV, they present studies on a second cohort of 15,831 patients admitted to 36 federally supported treatment agencies between June 1971 and May 1972. The findings presented here are comparable to those presented in the first two volumes. In the first year of treatment (we will have to wait for volume V for studies extending beyond one year), patients were able to decrease illicit drug use, become less criminally active, and improve their general functioning. However, they could not make significant gains in employment.

In these volumes the authors continue to refine the patient and treatment typologies they developed in the earlier volumes. Four basic treatment modalities are validated: methadone maintenance, therapeutic communities, drug-free treatment, and detoxification. Through the process of field study with identification of relevant factors and complicated statistical analyses the authors arrive at a sophisticated classification of treatments.

In methadone maintenance, for example, they describe two subtypes, methadone maintenance-change oriented (MM-CO) and methadone maintenance-adaptive (MM-A). The essential difference between these treatment approaches is that MM-CO programs place high demands on patient behavior while MM-A programs are "softer." These subtypes are easily identifiable from a clinical perspective, and, as the authors demonstrate, they are effective with different types of patients.

In volume IV a comparison of treatments indicates that methadone maintenance programs are superior to therapeutic communities, drug-free treatment, and detoxification in retaining patients in treatment. Surprisingly, MM-CO programs have higher retention rates than MM-A programs. The finding reported in volume IV that all treatments have some success and that different types of patients respond to different treatments is powerful confirmation of the multimodality concept. One hopes this will have a sobering effect on those who insist that their approach is the only one deserving funding. The data do not confirm the popular idea that alcoholism rates rise in drug-addicted patient populations. Little change was observed between the pretreatment and during-treatment prevalences of alcoholism. The findings in all four volumes of *The Effectiveness of Drug Abuse Treatment* highlight the need for combining treatment for drug abuse and social programming—social programming for repair of educational deficiencies and training for entry into the legitimate job market.

Sells and Simpson's work deserves the widest possible attention. It is methodologically sound, is based on large cohorts of addicts, and represents the best data we have. These data directly contradict the current widespread idea in the lay and medical press that drug abuse treatments, particularly methadone maintenance, are failures.

In addition to a contribution to the field of substance abuse, this work represents a landmark contribution to the assessment of social and mental health services. It will serve as a model for the continuing effort of evaluation and improvement of service efforts for many years to come. Dr. Lois Chatham of the U.S. Department of Health, Education, and Welfare is to be commended for her foresight in generating this effort.

EDWARD C. SENAY, M.D.

Alcohol and Alcohol Problems: New Thinking and New Directions, *edited by William J. Filstead, Jean J. Rossi, and Mark Keller. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 291 pp, $15.00.*

This book emanates from a 1973 conference at the Alcoholism Rehabilitation Center of Lutheran General Hospital in Des Plaines, Ill. Thus it suffers from the usual defects of such an arrangement: the contributions are four years old and the chapters are uneven, repetitious and, in some cases, in need of editorial surgery.

The book starts out with two interesting historical reviews by Mark Keller and Robert Strauss. Headway is lost, however, in a chapter by Seldon Bacon that, because of its length and wordiness, tends to lose the reader.

Henry Murphree's chapter, "Some Possible Origins of Alcoholism," is in my opinion the high point of the book. In an admirably succinct manner, Murphree reviews the state of knowledge on this vital topic and makes some important observations; e.g., that addiction is not a sufficient reason for alcoholic individuals to continue to drink or to return to drinking after abstinence. His comments about the high achieved with alcohol are worthy of a direct quotation:

> This state is more or less pleasant to large numbers of people, and to my mind it is probably the most common reason why people drink alcoholic beverages. For most, it is merely a harmless, transient state, and the regression may indeed be adaptive. But for some it seems to become so compelling as to override all other considerations, even the elementary needs for food, clothing, and shelter.

How sensible a point of view, yet it has been of only modest interest to clinical researchers.

Mello's chapter on biological research is a brief review that is to a degree repetitive of Murphree's. Of greatest interest here is the possibility that the presence of type IV lipoprotein abnormality may be a marker for people at greatest risk for alcohol-induced injury to the liver, heart, and pancreas. Mello is particularly concerned that basic research, which I gather means biological research, is not being given sufficient weight through federal research funding. She sees some arrogant, faceless bureaucracy as behind this, which will come as a surprise to those conscientious scientists who review proposals and assign priorities to them.

Rossi and Filstead critically review the present state of the art of diagnosis and treatment; they are not very complimentary. They describe the uses of labels and the demand that patients fit them and copouts on treatment failures by blaming the patient's lack of motivation. They also observe that the personal characteristics of the therapist are more important than training and credentials. Although these are reasonably correct observations, I felt they could have been somewhat softened.

The chapter on evaluation by Schuckit and Cahalan is the second high point of the book. It is a primer on program evaluation and a critique of past efforts that would be very helpful to someone about to embark on testing the effectiveness of his or her program. Their plea that we not confuse true program effectiveness with cost-benefit analysis is important today in light of the fact that business managers are invading the health care field with their eyes glued to the bottom line rather than focused on the best treatment outcome.

In the last chapter Gusfield tackles the toughest issue of all—prevention. One can hardly fault him for coming up empty. His observations are that nothing seems to have worked and that projects greeted with optimism have turned out to be "Hawthorne effects." He makes an intriguing suggestion that, lacking a primary prevention strategy, we should put our money into building a world in which alcohol-impaired people are less likely to come to grief. Examples are safer cars and highways and a restructuring of the work week to leave more days for drinking without experiencing absenteeism.

In total, although the subtitle of this book may not have been realized, the general quality of the book—the effort expended by those at the conference—makes it a useful addition to the library of alcohologists.

ROBERT A. MOORE, M.D.
San Diego, Calif.

Rorschach Content Interpretation, *by Edward Aronow, Ph.D., and Marvin Reznikoff, Ph.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1976, 340 pp., $19.50.*

The primary purpose of this text is to call attention to "content approaches" of the Rorschach test. According to the introduction, "Hermann Rorschach favored the perceptual factors, and the major emphasis of the Rorschach

schools and Rorschach textbooks has, likewise, been on perceptual factors" (p. xii).

The Rorschach sophisticate reading this text will find it difficult to avoid musing over the history of Roschach's test and the tomes of literature that emerged following the publication of his original text in 1921. *Rorschach Content Interpretation*, by virtue of its erudite format, is equally a tribute to the history of Rorschach's test as it is to the contemporary issues of content interpretation. In the fact that it discusses idiographic concepts (content), this text revisits the belabored issues of the nomothetic versus the idiographic approaches to the study of personality originally described by Allport in 1937. This book gives testament to the fact that the idiographic data of content can be evaluated as well within a nomothetic framework, even though measures of reliability and validity have not proven consistently promising.

This volume is considered the fullest attempt to document, classify, and evaluate the majority of the tomes of literature concerning interest content. Its publication is heralded even from the point of view of its use as a reference source. Beginning with a brief history of inkblot techniques (chapter 1), the authors introduce a variety of approaches in studying content interpretation. They start with the inception of such interpretation by the original investigator, referencing all of the pertinent literature published since concerning each individual method and evaluating the current status of the validity and reliability of each. They accomplish this task with scholarly erudition. The passing parade of Rorschach investigators cited for their original contributions of a variety of content scales in their own research efforts are too numerous to cite in this review; the list would comprise a Rorschach test anthology in itself.

This text opens with a lamenting tone of despair in citing Buros' poignant discounting of the validity of Rorschach's test (p. 1). It closes with a note of equal despair: Laurance Shaffer comments that the test never fulfilled its promise (p. 312). The authors state,

> Clinical Psychology has been led down a blind alley in electing to approach the Rorschach Test primarily from a perceptual standpoint. It is our hope that with the emphasis placed primarily on content and the analysis of verbalizations, the Rorschach Test will, in deed, fulfill its promise as a significant valid instrument." (p. 315)

They conclude that the Holtzman Inkblot Test (HIT) is more amenable to research use, the Rorschach more to clinical applications.

Although Rorschach emphasized the function of perception in his test, he also referred to apperception. The apperceptive functions (such as content) are still partially a function of the perceptual processes in each of the 10 test figures. In fact, chapter 11, which discusses the stimulus characteristics of the Rorschach blots, attests to this interdependency. The validity and reliability of content interpretation is partially dependent on the perceptual stimuli afforded by each card for which there are normative data.

It is surprising that the authors did not seize on the opportunity to refer to one of the most natural and logical theoretical frameworks to emphasize the interdependence between perception and interest content in the Rorschach, i.e., the Gestalt theory of perception. All of the Gestalt processes of leveling, sharpening, and normalizing, basic to the "law of Pregnanz" are involved in the final emergence of interest content to any one specific detail. In this respect, an innovative and most provocative use of Rorschach content from a psychotherapeutic as well as research point of view awaits those who apply the principles of Gestalt psychotherapy to the content interpretation of the Rorschach, especially from the point of view of innovative therapeutic strategies.

H. BARRY MOLISH, PH.D.
Houston, Tex.

Methods in Brain Research, *edited by Philip B. Bradley. New York, N.Y., Wiley-Interscience (John Wiley & Sons), 1975, 544 pp., $47.50.*

In the past quarter century neurobiology has expanded its body of knowledge at an exponential rate. As a result, it is now appropriate to ask not only what is known but how it is known. Because neurobiology has attracted workers from diverse disciplines, the editor of *Methods in Brain Research* concluded that a volume was needed on multidisciplinary approaches to brain research with an emphasis on methodology. During the genesis of this work, several multivolume works on method have appeared. These works plus the desire to limit this effort to a single volume led the editor to choose areas in which important methodological advances have recently been made.

A listing of the chapter headings will give an impression of the diversity of techniques discussed. The volume opens with a chapter on neuroanatomical methods; this chapter focuses on methods of selectively staining various neural structures. Chapters on autoradiography, subcellular fractionation, and microchemical techniques follow. A chapter on cytofluorometry describes microspectrofluorometric analysis, which has been spectacularly used by Swedish workers. A chapter cryptically titled "Collection Techniques" deals with the isolation of active substances, usually neurotransmitters. Electrophysiology has become old hat and receives attention only in a discussion of microelectrode techniques. The last of the micromethods deals with using tissue culture to provide various "model" neural systems. The four remaining chapters deal with behavioral techniques, including operant conditioning; a relatively brief chapter on the study of memory consolidation using intracranial self-stimulation; neuroethology, which addresses itself to the role of neural mechanisms in the normal behavior of animals in their natural environment; and an exceedingly brief chapter on psychosurgery.

The volume traverses the usual perils of a work by many authors. The editor has rejected the cookbook approach, but the individual authors have interpreted this mandate with varying degrees of rigor ranging from such descriptions as "centrifuge 56,000g × 120 min, synaptic membranes recoverable from the 1.2–1.0 and the 1.0–0.9 M interfaces" to an introspective, unfocused, and inconclusive attempt to decide whether or not "psychosurgery" should be performed on human beings. Chapters that fall in between such extremes prove useful and can provide a deeper understanding of the bases and limitations of various methodologies in neurobiology. On balance, the volume may fall to the charge that it is too complex for the uninitiated and inadequate for the cognescenti.

Dallas, Tex.

The Handbook of Gestalt Therapy, *edited by Chris Hatcher and Philip Himelstein. New York, N.Y., Jason Aronson, 1976, 795 pp., $25.00.*

The publication of a handbook is an important event for a body of knowledge because it indicates a new maturity. Thus the appearance of *The Handbook of Gestalt Therapy* is to be greeted with enthusiasm by those who have been interested in and followed the development of the subject. This handbook should be especially useful to those seeking to learn about Gestalt therapy for the first time. Articles by Joen Fagan and Claudio Naranjo on technique deserve special attention for their clarity and incisiveness; there are also many other excellent papers. A special strength of the book is its excellent index—something that has been sadly lacking in previous writings on Gestalt therapy. There is also a rather complete listing of films, audiovisual materials, and writings available on the subject. The book is divided into four parts: The Contributions of Frederick S. Perls, Contemporary Theory, Techniques, and Perspectives and Resources.

This handbook is really a collection of previously published articles on Gestalt therapy from books and journals. Only 11 of the 32 chapters were written specifically for the handbook. Although generally good, the work is marred by the spotty quality of some of the chapters. leaving the reader to wonder why they were included at all. It is also difficult to understand why the authors selected these articles to represent the whole of Gestalt therapy. For example, in 200 pages on the contributions of Perls, 1 chapter was selected from each of 3 of his books, *Gestalt Therapy Verbatim* (1), *Gestalt Therapy* (2), and *In and Out of the Garbage Pail* (his autobiography) (3). No explanation is given for the selection of these chapters over others. The grouping of articles that were written for many different purposes produces a hodgepodge of styles that detracts from the book's readability. One might say that the book as a whole does not form a very cohesive Gestalt (sic).

The editors of the handbook, who are Gestalt therapists, manifest in this volume an often observed phenomenon. True to their therapeutic perspectives, Gestalt therapists often write for themselves rather than for the reader. They are concerned with the experience of writing rather than with the product itself, thereby placing the purposes of therapy and publication in conflict. This book is representative of many of the problems with Gestalt therapy writings. Authors seem to be less concerned with a smoothly reading product than with the process and experience of production. For example, an interview with Jim Simkin about the history of Gestalt therapy contains five different notations such as "(unclear)" and "(too low)" on the first page. Would it really have been too much to expect of the editor to return to the source to obtain an understandable response?

In the last section of the book an article by Steven Applebaum compares psychoanalysis with Gestalt therapy and reveals the obvious: the two are much more closely related than the proponents of either have been willing to admit. It has always seemed that Gestalt therapy could easily be viewed as an extension of psychoanalytic ego psychology if it had not been for matters of personality and power. The separation of these bodies of knowledge is more political than theoretical, and each is poorer for it.

Mental Health Information Systems: Design and Implementation, *by David J. Kupfer, Michael Levine, and John A. Nelson. New York, N.Y., Marcel Dekker, 1976, 151 pp., $19.50.*

This book is the 19th volume in a series of monographs and textbooks on library and information science edited by Allen Kent, Director of the Office of Communication Programs at the University of Pittsburgh. In five chapters the authors present an overview of information systems and mental health programs that includes system design considerations, suggestions on how to support an information system, and a description of the development of specific systems at the Connecticut Mental Health Center in New Haven and the Western Psychiatric Institute and Clinic in Pittsburgh. In these times of strange bedfellows—administrators, insurance carriers, government, accreditation agencies, lawyers, and enormous health care delivery systems—the book presents a valuable overview of what to do and what to avoid in the development of a comprehensive information system.

Although the authors assert that the primary aim of a management information system in mental health should be the improvement of patient care, and some of Kupfer's research papers may certainly achieve that goal, the reader is left with the feeling that, at present, such systems are primarily useful to placate and relate with management, administration, insurance carriers, government accreditation agencies, and the law. Thus a management information system is a series of carefully planned procedures that facilitate the systematic gathering of data that can be processed into information that, in turn, enables people to make the institution run effectively. The management information system is actually used for the following purposes: 1) to produce reports for the charts, 2) to monitor quality of care, 3) to provide a data base for evaluation studies and clinical research, 4) to gather data in order to strengthen the fiscal system, 5) to provide data for administrative planning, and 6) to provide information for teaching.

From reading this book one senses the critical interstitial role of information as an administrative and management tool, as a means of interdisciplinary communication, and as a necessity for accountability, peer review, and audit studies. Its impact on patient care is very hard to evaluate.

Of considerable interest are the historical insights into the development of the systems in Connecticut and Pittsburgh. The evolution of the position of director of information at Pittsburgh and the single-portal entry system for workup and case disposition described are particularly worthy of consideration. The book is recommended as an introduction to the KDS forms and charting system. These should be seriously considered by all who anticipate changing currently inadequate medical records.

In the psychoneurotic patient, the pattern of anxiety – psychophysiological complaints and secondary depressive symptoms – often responds to Valium®(diazepam)

ROCHE

Before prescribing, please consult complete product information, a summary of which appears on the following page.

In the psychoneurotic patient

Valium® (diazepam) IV

2-mg, 5-mg, 10-mg scored tablets

can relieve anxiety and its secondary depressive symptoms

Initial calming in hours

Your anxious psychoneurotic patient will find the prompt antianxiety action of Valium (diazepam) highly reassuring. It's immediate, tangible proof that his medication is working.

Significant improvement in days

As Valium reduces overwhelming symptoms of anxiety and psychic tension, your patient begins to feel better often within a few days.

Patient response you know, want and trust

You've come to expect a certain kind of response with Valium—and that's the kind you usually get. A pronounced antianxiety response. A response that starts to benefit the anxious patient almost immediately.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

***Usage in Pregnancy:* Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Single copy, $4.00; 10–49 copies; $3.80 each; 50 or more copies, $3.20 each.

SPECIAL OFFER: One copy of this book (regular price, $4.00) and one copy of **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (regular price, $6.50) for $8.50.

Phillip H.* was an engineer with a problem... but now he's solving problems for industry

Patient name Phillip H.*	**Sex:** Male	**Age:** 29
Marital status S. (M.) W. D.	**Occupation:** Mechanical engineer	

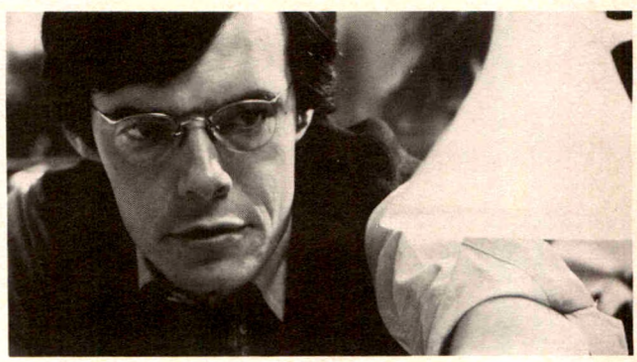
History:	Studious, bright, only son; much older sister. Father an invalid; mother, a successful business woman. A "loner" with multiple psychosomatic illnesses, he started dating late and married first girl friend, several years older
Onset of illness:	Upset at wife's pregnancy, expressed strong guilt feelings after her miscarriage; said people accused him of "murder." Unable to eat or sleep properly, felt he was "losing his mind." Unable to work, obtained leave of absence and was referred to psychiatrist
Diagnosis:	Acute schizophrenia
Treatment:	LOXITANE® Loxapine Succinate 25 mg b.i.d. increased to 50 mg t.i.d. over 2 weeks. Supportive psychotherapy three times a week
Therapeutic course:	First week, eating and sleeping better. Guilt feelings expressed less often. Mild akathisia responded to appropriate antiparkinson medication
	Second week, communicating better. Feared that "fatherhood would develop into rivalry," feared loss of wife's love
	Third week, no delusions or hallucinations, relating better, but still to only one person at a time
	Affect still blunted at one month, otherwise asymptomatic. LOXITANE decreased to 50 mg b.i.d.; antiparkinson medication continued
Follow-up:	10 weeks; at work for one week, seems to be adjusting well. Antiparkinson medication discontinued; psychotherapy weekly, LOXITANE 25 mg t.i.d.

*Not an actual patient. The collection of clinical data upon which this simulation is built illustrates the action of LOXITANE® Loxapine Succinate as reported in clinical studies.

He's adjusting well in his job, and with psychotherapy and medication, he also can be helped to feel more secure, less threatened in his relationships with others.

Loxitane®
LOXAPINE Lederle SUCCINATE

For the symptoms that interrupt careers



See LOXITANE prescribing information on following page for indications, warnings and precautions and for more detailed information concerning side effects.

Loxitane®
LOXAPINE SUCCINATE
Lederle

For the symptoms that interrupt careers

Recommended Daily Dosage

Initial Dosage	MILD 10 mg b.i.d.	MODERATE 10 mg t.i.d. or q.i.d.	SEVERE 25 mg b.i.d.
First 7 to 10 Days	Increase dosage until psychotic symptoms are controlled. Dosage should not exceed 250 mg/day. Usual dosage during titration: 50 to 150 mg/day.		
Maintenance Dosage	Adjust to lowest effective level. Usual maintenance dosage: 60 to 100 mg/day. Many patients are controlled with dosages as low as 20 to 60 mg/day.		

Brief Summary

LOXITANE® Loxapine Succinate Capsules
OR
LOXITANE® C Loxapine Hydrochloride Oral Concentrate

Description: A dibenzoxazepine compound, representing a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines.

Indications: For the manifestations of schizophrenia. Loxapine has not been evaluated for the management of behavioral complications in mental retardation, and therefore cannot be recommended.

Contraindications: In comatose or severe, drug-induced depressed states (alcohol, barbiturates, narcotics, etc.); and in individuals with known hypersensitivity to the drug.

Warnings: In Pregnancy: Safe use during pregnancy or lactation has not been established; in pregnancy, nursing mothers, or women of child-bearing potential, weigh potential benefits against possible hazards to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from mid-pregnancy with doses of 0.6 and 1.8 mg./kg., doses which approximate the usual human dose but which are considerably below the maximum recommended human dose. **In Children:** Studies have not been performed in children; therefore this drug is not for use below the age of 16.

May impair mental and/or physical abilities, especially during the first few days of therapy; warn ambulatory patients about activities requiring alertness (*e.g.*, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

Precautions: Use with extreme caution in patients with history of convulsive disorders; seizures have been reported in epileptics receiving this drug at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy. Has an antiemetic effect in animals; this effect in man may mask signs of overdosage of toxic drugs and obscure conditions such as intestinal obstruction and brain tumor. Use with caution in patients with cardiovascular disease. Increased pulse rates in the majority of patients receiving antipsychotic doses and transient hypotension have been reported. In hypotension requiring vasopressor therapy, preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine. Possibility of ocular toxicity from loxapine cannot be excluded at this time, therefore observe carefully for pigmentary retinopathy and lenticular pigmentation (observed in some patients receiving certain other antipsychotic drugs for prolonged periods). Because of possible anticholinergic action, use with caution in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

Adverse Reactions: CNS: Adverse effects other than extrapyramidal, infrequent. Drowsiness, usually mild, may occur at beginning of therapy or when dosage is increased, usually subsiding with continued therapy. Incidence of sedation is less than that of certain aliphatic phenothiazines and slightly more than piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported. Extrapyramidal reactions during use of this drug have been reported frequently, often during the first few days of treatment. In most patients, these involve Parkinson-like symptoms such as tremor, rigidity, excessive salivation, masked facies, akathisia, usually not severe and controlled by dosage reduction or use of antiparkinson drugs in usual dosage. *Less frequent, but more severe:* Dystonias, including spasms of muscles of neck and face, tongue protrusion, oculogyric movement; dyskinesia in the form of choreo-athetoid movements. These sometimes require reduction or temporary withdrawal of drug dosage in addition to appropriate counteractive drugs. *Persistent Tardive Dyskinesia:* May appear in some patients on long-term therapy, or after therapy has been discontinued; the risk greater in the elderly, especially females, on high dosage. These symptoms, persistent and in some patients apparently irreversible, are characterized by rhythmical involuntary movement of tongue, face, mouth or jaw (*e.g.*, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements, sometimes accompanied by involuntary movements of extremities). No known effective treatment; discontinue all antipsychotic agents if these symptoms appear. The necessity to reinstitute treatment or increase dosage, or switch to a different antipsychotic agent, may mask syndrome. If medication is stopped when fine vermicular movements of the tongue occur, the syndrome may not develop. *Cardiovascular:* Tachycardia, hypotension, hypertension, lightheadedness, syncope. A few cases of EKG changes similar to those seen with phenothiazines have been reported, not known to be related to loxapine use. *Skin:* Dermatitis, edema (puffiness of face), pruritus, seborrhea. Possible photosensitivity and/or phototoxicity; skin rashes of uncertain etiology seen in a few patients during hot summer months. *Anticholinergic:* Dry mouth, nasal congestion, constipation, blurred vision—more likely to occur with concomitant use of antiparkinson agents. *Other:* Nausea, vomiting, weight gain or loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, polydipsia. Rarely, galactorrhea and menstrual irregularity of uncertain etiology.

Dosage and Administration: Administered orally, usually in 2 to 4 divided doses a day. Adjust dosage to patient's need relative to severity of symptoms and history of response to antipsychotic drugs. Recommended initial dosage is 10 mg. b.i.d.; in severely disturbed patients up to 50 mg. daily. Increase dosage during first 7 to 10 days until psychotic symptoms are controlled. Usual therapeutic and maintenance range is 60 mg.-100 mg. daily. More than 250 mg. daily is not recommended. Maintenance dosage should be at lowest level to control symptoms; many patients have been maintained on 20 mg. to 60 mg. daily.

LOXITANE C Oral Concentrate should be mixed with orange and grapefruit juice shortly before administration. Use only enclosed calibrated dropper.

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

Patients become easier to manage

...with a low incidence of adverse side effects on

MOBAN®
molindone HCl

- an effective antipsychotic agent
- not a phenothiazine

FAVORABLE BENEFIT/RISK PROFILE, WHICH MAY ENHANCE COMPLIANCE*

NO incidence	Tolerance development Hepatotoxic changes Ophthalmological changes Excessive weight gain Impotence Decreased libido Skin pigmentation Thyroid function changes Persistent tardive dyskinesia
LOW incidence	Sedation Adverse drug interactions Hypotension Hematological changes Lactation Amenorrhea Autonomic changes Skin rash Nonpersistent symptoms of tardive dyskinesia
MODERATE incidence	Extrapyramidal reactions

*This table compiled from clinical and field reports, according to the best available information.

Further advantages with MOBAN®

The pharmacological effect from a single oral dose persists for 24-36 hours, permitting *h.s.* dosage, once the daily dosage level is established.

Several clinicians have reported that obese patients on MOBAN® frequently experienced a marked reduction in weight toward normal weight.

How to use MOBAN®

The usual starting dose is 50-75 mg/day. You can increase to 100 mg/day in 3-4 days. Titrate individually up or down depending on patient response. Some chronic, treatment-resistant patients may require an increase to 400 mg/day. (However, the long-term safety of 400 mg/day has not been established.) Please refer to complete prescribing information for further dosage instructions.

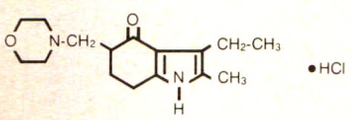
DUPONT

Patients become easier to manage on



MOBAN®

molindone HCl

5 mg	10 mg	25 mg
Endo	Endo	Endo

DESCRIPTION MOBAN® (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN® is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN® (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN® antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN® exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN® (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN® being excreted in urine and feces.

INDICATIONS MOBAN® (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN® (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in the pregnant patient have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose— 20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose— 20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose— 5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN® (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN® (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS Some patients receiving MOBAN® (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN®. Caution should be exercised where increased activity may be harmful.

MOBAN® does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN® has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological

Extrapyramidal Reactions

Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia

Motor restlessness may occur early.

Parkinson Syndrome

Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome

Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System

Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological

There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN® may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects

Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with MOBAN® therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN®.

Cardiovascular

Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological

Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN® (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN®.

Skin

Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN® usage alone.

MOBAN® (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN® is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia

Although rarely reported with MOBAN® (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN® (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50-75 mg/day.

—Increase to 100 mg/day in 3 or 4 days.

—Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.

—An increase to 225 mg/day may be required in patients with severe symptomatology.

—Some chronic, treatment resistant patients, may require up to 400 mg/day (however, the long term safety of 400 mg/day has not been established).

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

Dosages may be administered once a day.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN® (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN® is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN® (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN® (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN® in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN® from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN® is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN® in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles of 100 and 1000 with potencies and colors as follows: 5 mg orange, 10 mg lavender, 25 mg light green.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

trifluoperazine HCl
in Psychiatry."

Messenger Mask, Dene culture, Anvik, Alaska. Festival mask representing legendary cannibal woman's son who lured victims for his mother.
From the collection of the University Museum, University of Pennsylvania, Philadelphia, Pa. Reproduced with permission.

REMOVE THE MASK OF SCHIZOPHRENIC SYMPTOMS

'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY AND OTHER SCHIZOPHRENIC SYMPTOMS IN A WIDE RANGE OF PATIENTS.

FROM THE WITHDRAWN AND APATHETIC TO THE ANXIOUS AND OVERACTIVE, 'STELAZINE' HELPS RETURN THE PSYCHOTIC PATIENT TO REALITY AND CAN FACILITATE THERAPEUTIC CONTACT AND RAPPORT.

- EFFECTIVELY CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

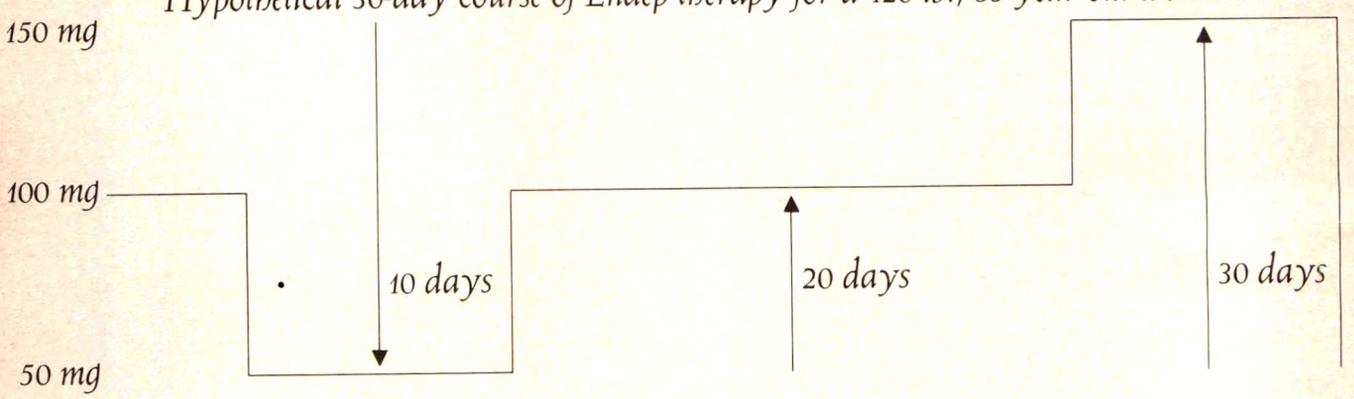
Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

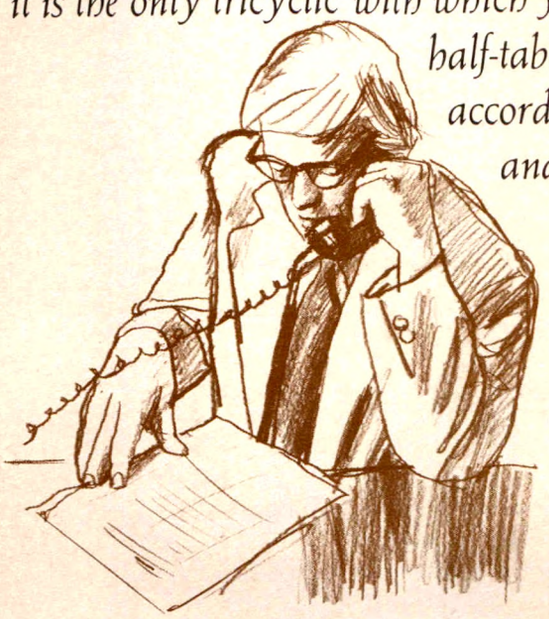
SK&F CO.



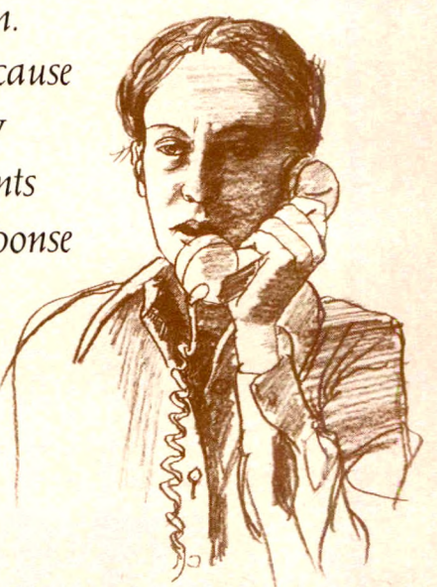
Manufactured and distributed by SK&F Co., Carolina, P.R. 00630 under Stelazine® trademark license from SmithKline Corporation

brand of **STELAZINE®**
TRIFLUOPERAZINE HCL
Tablets: 5 and 10 mg

Helps schizophrenic patients become more responsive.



Why Endep® makes with amitriptyline HCl

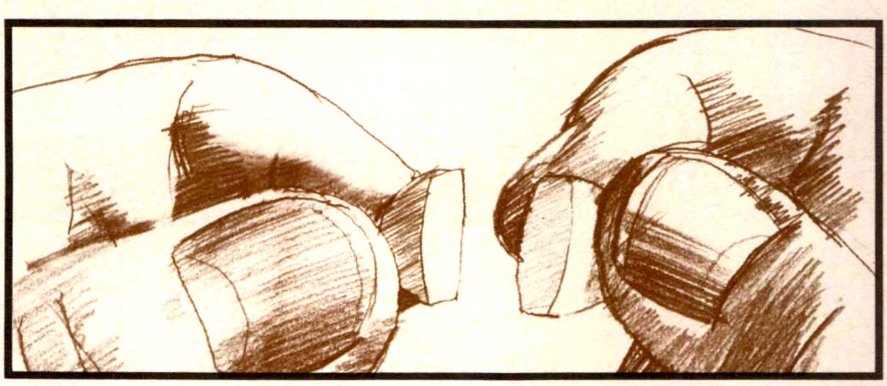


Hypothetical 30-day course of Endep therapy for a 120 lb., 35-year old woman.

Half-dose adjustments h.s., depending on progress or side effects.

Because therapeutic levels of amitriptyline vary greatly from patient to patient, reaching the optimal dose requires careful titration. Endep (amitriptyline HCl) greatly facilitates this process because it is the only tricyclic with which you can adjust dosage by half-tablet increments or decrements according to the therapeutic response and/or side effects.

ROCHE



titration more practical:

Flexibility promotes optimal response and economy

The wide range of six different tablet strengths—from 10 mg to 150 mg—permits you to prescribe the strength best suited for the individual patient. Because you won't need a new Rx, you can save your patient the cost of an extra prescription fee. And, by prescribing the daily dose at bedtime, you can prescribe the higher strength at the outset and help the patient economize on the prescription price per milligram.

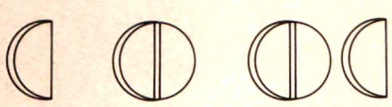
Scored tablets obviate need for new Rx

Half-tablet dosage adjustments with Endep (amitriptyline HCl) are possible because every tablet is scored. You can prescribe a single strength and still have the advantage of adjusting dosage without resorting to a new Rx.

Endep®

amitriptyline HCl/Roche

The half-strength advantage



Before prescribing, please consult complete product information, a summary of which appears on the following page.

Practicality is a fundamental fact about Endep®

amitriptyline HCl/Roche

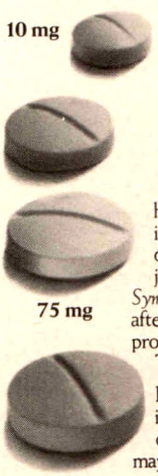
Every tablet of Endep (amitriptyline HCl) is scored for precise, convenient adjustment of dosage.

Half-tablet adjustment of dosage does not require a new Rx.

Single daily *h.s.* dosage promotes compliance and economy.

Compliance with practical regimen promotes optimal response.

Before prescribing, please consult complete product information, a summary of which follows:



Indications: To relieve symptoms of depression (notably endogenous depression) and depression accompanied by anxiety.

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle-closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels.

Other: Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Dosage: Initiate at low levels, increase gradually, watching for signs of intolerance. As long as 30 days may elapse before adequate antidepressant effect develops; sedative effect may be noted earlier.

Initial Adult Dosage: Outpatients—25 mg *t.i.d.*; may be increased to 150 mg/day. Add increased drug to afternoon and/or bedtime doses. Alternate—50 to 100 mg *h.s.*, gradually increasing *h.s.* dose up to 150 mg/day. Hospitalized Patients—Up to 100 mg/day; increase gradually to 200 mg if necessary. A few patients may require 300 mg/day.

Adolescent and Elderly Patients: In general, 10 mg *t.i.d.* with 20 mg *h.s.* may be satisfactory for those who do not tolerate higher doses.

Maintenance Dosage: With symptomatic improvement, reduce dosage to lowest amount that gives relief, usually 25 mg *b.i.d.* to *q.i.d.*, or 10 mg *q.i.d.* Continue maintenance therapy 3 months or longer to avoid relapse.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. IV administration of 1 to 3 mg physostigmine salicylate reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestations and treatment.

Supplied: 10-mg, 25-mg, 50-mg, 75-mg, 100-mg and 150-mg scored tablets—bottles of 100 and 500; Tel-E-Dose® packages of 100; Prescription Paks of 60 (10 mg, 25 mg and 50 mg) or 30 (75 mg, 100 mg and 150 mg), available singly and in trays of 10.

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

Director of Rehabilitation Services

Brentwood-UCLA Psychiatric Teaching Hospital is seeking Director of Rehabilitation Services, serving 400 inpatient and 2300 outpatients. Psychiatrists, Physiatrists, or other disciplines may apply. Services include Vocational testing, counseling, placement, and training programs, sheltered workshop, occupational therapy, education, recreation, and community projects. Experience in program development and management required, must qualify for UCLA faculty appointment. Involvement in teaching and research encouraged. Salary commensurate with qualifications; plus generous U.S. Government fringe benefits; licensure in any state acceptable; an opportunity for professional growth and personal enrichment in a fine seaside community with clean air and unexcelled academic, cultural and recreational resources. Write Milton Greenblatt, M.D., Chief of Staff, VA Hospital, Brentwood, Wilshire & Sawtelle Blvds. 530/11D, L.A., CA 90073 Phone 478-3711, Ext. 1641, Equal Opportunity Employer

DIRECTOR

SAGAMORE CHILDREN'S PSYCHIATRIC CENTER
LONG ISLAND, NEW YORK

Salary: $43,834
plus fringe benefits

The N.Y.S. Dept. of Mental Hygiene is seeking a full time director for the above facility.

Applicants must have extensive professional experience in providing services to mentally ill children and adolescents; a substantial part of which must be in a capacity demonstrating organizational and administrative skills in the treatment setting. Minimum educational requirements include an appropriate professional degree plus N.Y.S. license or certification where applicable; medical board certification necessary for physicians.

Send detailed resume by Sep. 12, 1977, to
John J. Lagatt, Assistant Commissioner
N.Y.S. Dept. of Mental Hygiene
44 Holland Ave. Albany, N.Y. 12229
An equal opportunity employer

PSYCHIATRIST — BOARD ELIGIBLE

Clinical position on the treatment team of our 5 year old comprehensive community mental health center. Inpatient services include units for psychiatric long term care, developmental disabilities and acute care. Outpatient services encompass child treatment, day hospital, biofeedback, neuropsychology, outpatient counseling and therapy services as well as consultation and education to the community. Salary negotiable. Liberal fringe benefit package. Call or write L. H. Gombus, M.D., Clinical Director, Fond du Lac County Mental Health Center, 459 E. First Street, Fond du Lac, Wisconsin 54935. (414-921-5480). Equal opportunity employer.

BERMUDA
CONSULTANT PSYCHIATRIST

The Bermuda Hospitals' Board requires two (2) Consultant Psychiatrists for St. Brendan's Hospital to commence on 1st April, 1978. The Hospital is fully accredited by the Canadian Council for Hospital Accreditation.

The clinical team comprises four Consultants, two Resident Doctors, two Clinical Psychologists, four Mental Welfare Officers, five qualified Occupational Therapists, one Educational Therapist and a nursing establishment of 119 of which over half are fully qualified.

The hospital has 170 beds and is divided into eight distinct ward areas two of which care for the mentally retarded. It serves the total Island population of 60,000.

The theme of the psychiatric service is community oriented and an active rehabilitation programme is practiced. In addition, consulting services are provided to the Social Services Department, Sheltered Workshops, Child and Family Services, Rehabilitation Hostels, Drug and Alcohol Addiction Services, community based Geriatric Facilities, the Prison Services and the Island's modern General Hospital. Many of these programmes have recently been developed and there is therefore ample opportunity to develop and put into practice one's own interests and ideas.

Extra experience in psychogeriatrics, or neuropsychiatry would be valuable but not essential as, in selecting the candidate, emphasis will be on good all round psychiatric training and experience and the ability to share with colleagues the continued development of the service.

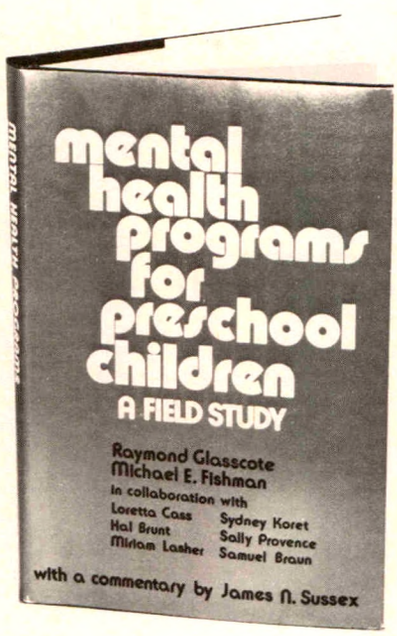
BENEFITS:

Salary: BD$27,164.00 p.a. (subject to review) (BD$=USA$)
October, 1, 1977)

In addition shared private practice, no income tax, minimal cost health insurance, settlement and baggage allowances and return air fares for the successful candidate and family.

Further information is available, on request.

Applications, which should include curriculum vitae and the names of three (3) references, should be forwarded to:



The Executive Director
Bermuda Hospitals' Board
King Edward VII Memorial Hospital
Paget 6-23
BERMUDA

to arrive by 31st October, 1977.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

Amphetamines work in MBD.
Methylphenidate works in MBD.

Then why Cylert® for MBD?

(pemoline)

Because Cylert offers a lot:

- Once-a-day dosage at home
- Elimination of mid-day school dose and need for school personnel supervision
- Avoids ups and downs of drug action brought about by multiple daily dosage
- Control of medication by the parent
- A chewable dosage form
- Less physician paper work (Cylert is in schedule IV)
- Safety and efficacy proven in extensive clinical studies*

*Copy of the Cylert Monograph available to Physicians on written request.

Dosage and administration

Cylert is administered as a single oral dose each morning.

The recommended starting dose is 37.5 mg/day. This daily dose should be gradually increased by 18.75 mg at one week intervals until the desired clinical response is obtained. The effective daily dose for most patients will range from 56.25 to 75 mg. The maximum recommended daily dose of pemoline is 112.5 mg.

Clinical improvement with Cylert is gradual. Using the recommended schedule of dosage titration, significant benefit may not be evident until the third or fourth week of drug administration. Drug administration should be interrupted occasionally (once or twice a year) to determine if behavioral symptoms are sufficient to require continued therapy.

When not to use medication

Cylert should not be used for (and will not be effective in) simple cases of overactivity in school age children.

Neither should it be used in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

The physician should rely on a complete history of the child and a thorough description of symptoms from both parents and teacher before postulating a diagnosis of MBD.

Cylert and Cylert Chewable Tablets

(pemoline)

Prescribing Information

Description: Cylert (pemoline) is a central nervous system stimulant. Pemoline is structurally dissimilar to the amphetamines and methylphenidate.

It is an oxazolidine compound and is chemically identified as 2-amino-5-phenyl-2-oxazolin-4-one.

Pemoline is a white, tasteless, odorless powder, relatively insoluble (less than 1 mg./ml.) in water, chloroform, ether, acetone, and benzene; its solubility in 95% ethyl alcohol is 2.2 mg./ml.

Cylert (pemoline) is supplied as tablets for oral administration.

Clinical Pharmacology: Cylert (pemoline) has a pharmacological activity similar to that of other known central nervous system stimulants; however, it has minimal sympathomimetic effects. Although studies indicate that pemoline may act in animals through dopaminergic mechanisms, the exact mechanism and site of action of the drug in man is not known.

The serum half-life of pemoline is approximately 12 hours. Peak serum levels of the drug occur within 2 to 4 hours after ingestion of a single dose. Multiple dose studies in adults at several dose levels indicate that steady state is reached in approximately 2 to 3 days.

Metabolites of pemoline include pemoline conjugate, pemoline dione, mandelic acid, and unidentified polar compounds. Cylert is excreted primarily by the kidneys; approximately 75% of an oral dose is recovered in the urine within 24 hours. Approximately 43% of pemoline is excreted unchanged.

Cylert (pemoline) has a gradual onset of action in children with minimal brain dysfunction. Using the recommended schedule of dosage titration, significant clinical benefit may not be evident until the third or fourth week of drug administration.

Indications: *MINIMAL BRAIN DYSFUNCTION IN CHILDREN*—as adjunctive therapy to other remedial measures (psychological, educational, social).

Special Diagnostic Considerations: The cause of minimal brain dysfunction (MBD) is unknown. Diagnosis of MBD involves the use of medical, psychological, educational, and social tools, since no single diagnostic test is adequate.

MBD is characterized by chronic moderate to severe hyperactivity, short attention span, distractibility, emotional lability, and impulsivity. Nonlocalizing (soft) neurological signs, learning disability, and abnormal EEG may or may not be present. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. In the primary therapy of MBD, appropriate educational placement is essential and psychosocial intervention is generally necessary. When these measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

Contraindications: Cylert (pemoline) is contraindicated in patients with known hypersensitivity or idiosyncrasy to the drug. (See ADVERSE REACTIONS.)

Warnings: Cylert is not recommended for children less than 6 years of age since its safety and efficacy in this age group have not been established.

Sufficient data on the safety and the efficacy of the long-term use of Cylert in children with minimal brain dysfunction are not yet available.

A temporary suppression of the predicted growth rate (weight and/or height gain) has been reported for children receiving long-term stimulant therapy. A definite causal relationship between stimulant drugs and this finding has not been established.

Precautions: Liver function tests should be performed periodically during therapy with Cylert. The drug should be discontinued if abnormalities are revealed and confirmed by follow-up tests. (See ADVERSE REACTIONS regarding reports of abnormal liver function tests and jaundice.)

Cylert should be administered with caution to patients with significantly impaired hepatic or renal function.

The interaction of Cylert with other drugs has not been studied in humans. Patients who are receiving Cylert concurrently with other drugs, especially drugs with CNS activity, should be monitored carefully.

Cylert failed to demonstrate a potential for self-administration in primates. However, the pharmacologic similarity of pemoline to other psychostimulants with known dependence liability suggests that psychological and/or physical dependence might also occur with Cylert. There have been isolated reports of transient psychotic symptoms occurring in adults following the long-term misuse of excessive oral doses of pemoline. Cylert should be given with caution to emotionally unstable patients who may increase the dosage on their own initiative.

Usage during Pregnancy and Lactation: The safety of Cylert (pemoline) for use during pregnancy and lactation has not been established.

Fertility, reproduction, and teratology studies were conducted in laboratory animals. Pemoline, in doses of 18.75 or 37.5 mg./kg./day, had no effect on the fertility of male or female rats. The drug, when given to pregnant rats (from gestation day 15 through weaning) and to rabbits (from gestation days 6-18) at these same dosage levels, produced no teratogenic or embryotoxic effects, and had no effect on the viability of the young at birth. However, increased incidences of stillbirths and cannabilization were observed when pemoline was given to rats at these dosage levels, beginning 14 days prior to conception.

Adverse Reactions: Insomnia is the most frequently reported side effect of Cylert; it usually occurs early in therapy, prior to an optimum therapeutic response. In the majority of cases it is transient in nature or responds to a reduction in dosage.

Anorexia with weight loss may occur during the first weeks of therapy. In the majority of cases it is transient in nature; weight gain usually resumes within three to six months.

Stomach ache, skin rashes, increased irritability, mild depression, nausea, dizziness, headache, drowsiness, and hallucinations have been reported.

Elevations of SGOT, SGPT, and serum LDH have occurred in patients taking Cylert, usually after several months of therapy. These effects appear to be reversible upon withdrawal of the drug, and are thought to be manifestations of a delayed hypersensitivity reaction. There have also been a few reports of jaundice occurring in patients taking Cylert; a causal relationship between the drug and this clinical finding has not been established.

There have been reports of dyskinetic movements of the lips, face, and extremities occurring with the use of Cylert. Convulsive seizures have also been reported. A definite causal relationship between Cylert and these reactions has not been established.

Mild adverse reactions appearing early during the course of treatment with Cylert often remit with continuing therapy. If adverse reactions are of a significant or protracted nature, dosage should be reduced or the drug discontinued.

Overdosage: Signs and symptoms of acute Cylert overdosage may include agitation, restlessness, hallucinations, tachycardia. The treatment for an acute overdosage of pemoline is essentially the same as that for an overdosage of any CNS stimulant. Management is primarily symptomatic and may include induction of emesis or gastric lavage, sedation, and other appropriate supportive measures.

Results of preliminary studies in dogs indicate that extracorporeal hemodialysis may be useful in the management of Cylert overdosage; forced diuresis and peritoneal dialysis appear to be of little value.

Dosage and Administration: Cylert (pemoline) is administered as a single oral dose each morning.

The recommended starting dose is 37.5 mg./day. This daily dose should be gradually increased by 18.75 mg. at one week intervals until the desired clinical response is obtained. The effective daily dose for most patients will range from 56.25 to 75 mg. The maximum recommended daily dose of pemoline is 112.5 mg.

Clinical improvement with Cylert is gradual. Using the recommended schedule of dosage titration, significant benefit may not be evident until the third or fourth week of drug administration. Drug administration should be interrupted occasionally (once or twice a year) to determine if behavioral symptoms are sufficient to require continued therapy.

How Supplied: Cylert (pemoline) is supplied as monogrammed, grooved tablets in three dosage strengths:

18.75 mg. tablets (yellow-colored) in bottles of 100 (NDC 0074-6025-13)

37.5 mg. tablets (orange-colored) in bottles of 100 (NDC 0074-6057-13)

75 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-6073-13)

Cylert Chewable is supplied as monogrammed, grooved tablets in one dosage strength:

37.5 mg. tablets (orange-colored) in bottles of 100 (NDC 0074-6088-13)

Just Published . . .

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

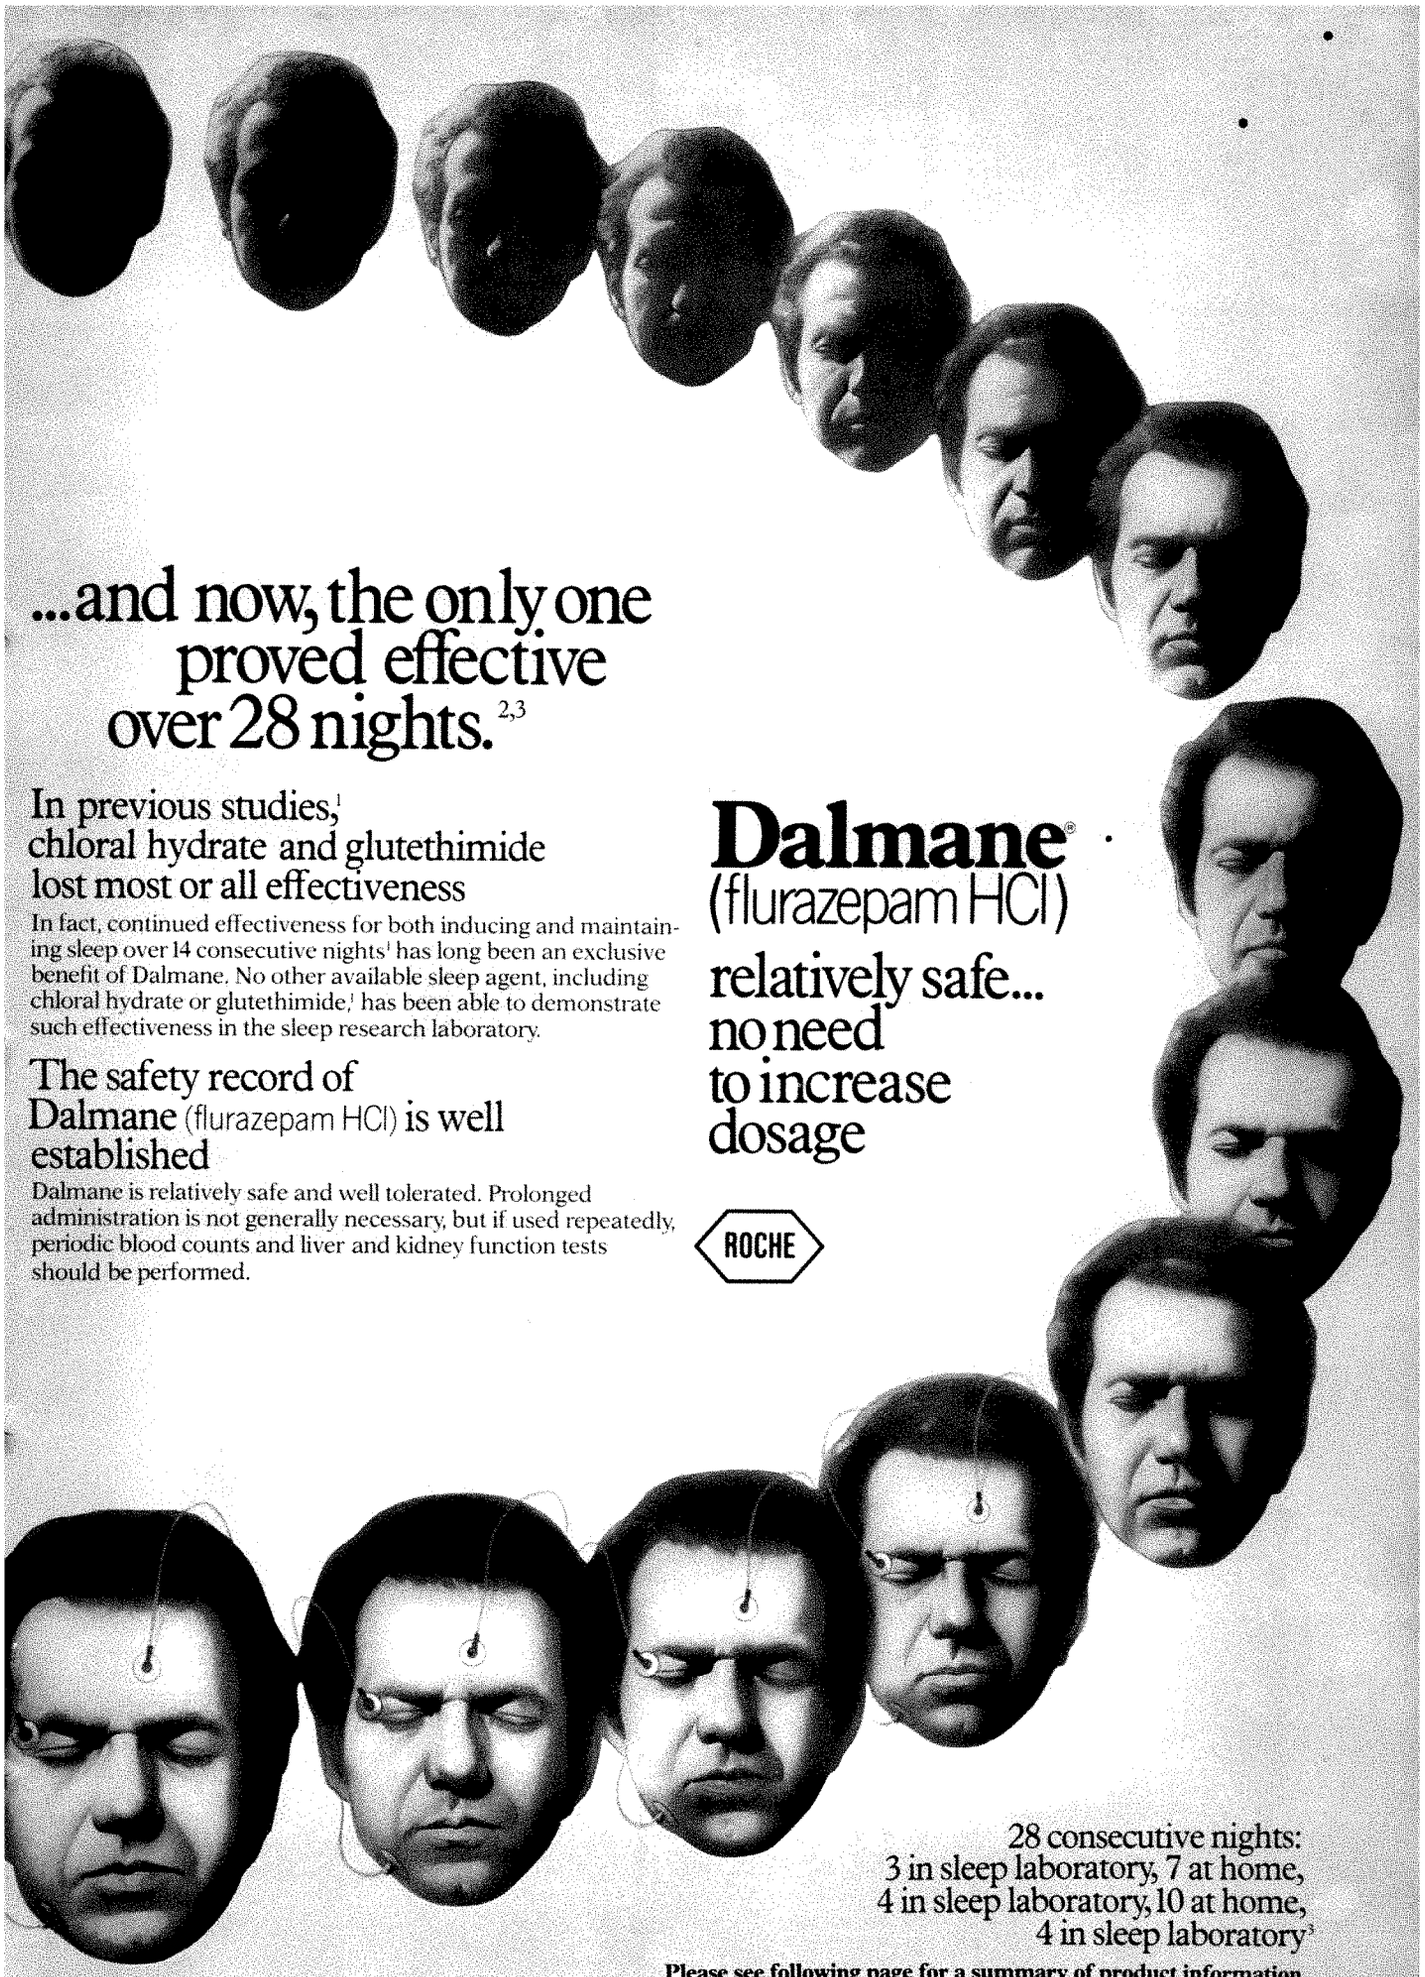
From the Sleep Research Laboratory:

Dalmane® (flurazepam HCl) proved the most effective hypnotic over 14 nights...[1]



TOTAL SLEEP TIME (MEAN)[3]
(5 patients with insomnia)

*Significantly increased over baseline placebo ($p < .05$)

For those patients who need it, Dalmane (flurazepam HCl) alone provides continued effectiveness[2,3]

Since insomnia is often transient and intermittent, the prolonged administration of a hypnotic is generally not necessary or recommended. But for those patients whose insomnia is a chronic problem, the continued effectiveness of Dalmane is a decided benefit. Even at the end of a 28-night medication period, patients with chronic insomnia were falling asleep faster, spending less time awake during the night, and sleeping substantially longer on Dalmane 30 mg *h.s.* than on baseline placebo nights (average results). This effectiveness was proved[2] and confirmed[3] in two independent sleep research studies using a new 47-night protocol. When similarly evaluated, pentobarbital was ineffective at the end of two weeks.[2]

14 consecutive nights:
3 in sleep laboratory, 8 at home,
3 in sleep laboratory

...and now, the only one proved effective over 28 nights.[2,3]

In previous studies,[1] chloral hydrate and glutethimide lost most or all effectiveness

In fact, continued effectiveness for both inducing and maintaining sleep over 14 consecutive nights[1] has long been an exclusive benefit of Dalmane. No other available sleep agent, including chloral hydrate or glutethimide,[1] has been able to demonstrate such effectiveness in the sleep research laboratory.

The safety record of Dalmane (flurazepam HCl) is well established

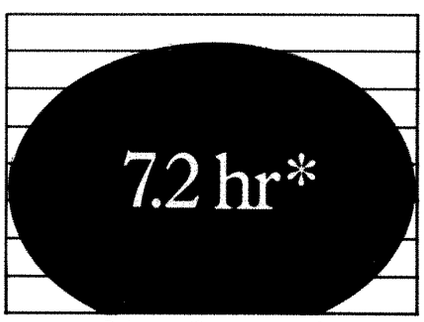
Dalmane is relatively safe and well tolerated. Prolonged administration is not generally necessary, but if used repeatedly, periodic blood counts and liver and kidney function tests should be performed.

Dalmane®
(flurazepam HCl)

relatively safe... no need to increase dosage

ROCHE

28 consecutive nights:
3 in sleep laboratory, 7 at home,
4 in sleep laboratory, 10 at home,
4 in sleep laboratory[3]



Please see following page for a summary of product information.

1,5,7,14,28 nights... as needed, the effectiveness of Dalmane® one *h.s.* (flurazepam HCl) C IV meets the challenge of insomnia

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

- **Patients fall asleep rapidly, sleep longer on a single *h.s.* dose**
- **Nighttime awakenings and time spent awake are reduced**
- **Effectiveness maintained without dosage increase from night to night**
- **Patients generally awaken refreshed; morning "hangover" is infrequent**

TOTAL SLEEP TIME (OVERALL MEAN)[3]
(5 patients with insomnia)

Dalmane (flurazepam HCl)
nights 1-3, 12-14, 26-28

*Significantly increased over baseline placebo ($p < .05$).

REFERENCES:

2. Kales A, *et al*: *Clin Pharmacol Ther* 18:356-363, Sep 1975
3. Dement WC, *et al*: Long-term effectiveness of flurazepam 30 mg *h.s.* on chronic insomniacs. Presented at the 15th annual meeting of the Association for Psychophysiological Study of Sleep, Edinburgh, Scotland, Jun 30-Jul 4, 1975

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:
Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.
Contraindications: Known hypersensitivity to flurazepam HCl.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).

***Usage in Pregnancy:* Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane (flurazepam HCl), a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.
Precautions: In elderly and debilitated, limit initial dosage to 15 mg to preclude oversedation, dizziness and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.
Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.
Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.
Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

ROCHE

ROCHE LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

"I'm just a shadow of what I used to be."

That is what depressed individuals may feel is the substance of their being. There is no pleasure, no joy – nothing grows – and in the cold shadow of depression their activities are inhibited, while initiative may be eroded or destroyed. The tragedy is that they can see that others are able to live on the brighter side but they, themselves, cannot reach it on their own.

Your experience in treating depression, and Tofranil-**PM** can help light the way.

Tofranil-**PM**®
imipramine **pamoate**

Geigy

Unsurpassed effectiveness among tricyclics in relieving symptoms of depression.

Before prescribing Tofranil-PM, please review a summary of the prescribing information on the back of this page.

A83

Tofranil-PM®
imipramine pamoate

Geigy

As sleep disturbances, fatigue, and other depressive symptoms are relieved, mood and motivation may be markedly improved.

Patients are usually alert and capable of functioning at more normal levels of behavior.

Tofranil-PM encourages patient compliance because one capsule lasts from bedtime to bedtime.

Good results are usually seen at the starting dose of one 75-mg capsule h.s.

For many patients, dosage can be safely increased to 150 mg daily.

As with all tricyclics, sedation may occur. Please caution patients against driving or operating dangerous machinery.

Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg of imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

"Now Andy's classmates laugh

with him, not at him"

Today, direct coaching in appropriate social interaction, role playing, and encounter techniques are being used to help hyperactive children overcome disruptive social behavior patterns that often cause them to become objects of ridicule to their peers.

Ritalin, when indicated, can also play a useful role in this respect, as improving social interaction in the MBD child often involves reducing hyperactivity. Indeed, as one investigator[1] has reported, with Ritalin therapy, the MBD child can be less aggressive, less impulsive, and better able to interact with his peers.

Other studies also report improved social behavior of MBD children on Ritalin.[2,3]

A drug of choice when treatment of MBD is indicated,[4,5] controlled studies and clinical experience have demonstrated the ability of Ritalin to effectively reduce hyperactivity,[1,2] distractibility,[1,3] and disorganized behavior[1,3,6-8] in the MBD child.

And these symptomatic improvements achieved with Ritalin often result in the child being more responsive to the nonpharmacological measures of the MBD management team.[8]

Although side effects – insomnia and appetite loss – are occasionally seen with Ritalin, they are less frequent or severe than with dextroamphetamine.[4,10]

Therapy with Ritalin should be undertaken only after a medical diagnosis of MBD has been made. Dosage should be periodically interrupted. Often these interruptions reveal some "stabilization" in the child's behavior even without medication. In some MBD children they permit a reduction in dosage and eventual discontinuance of drug therapy.

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Symptoms of visual disturbances have been encountered in rare cases. Difficulties with accommodation and blurring of vision have been reported.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over).

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-Pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

CIBA

Tranxene® CL IV

CAPSULES
SINGLE DOSE TABLETS

CLORAZEPATE DIPOTASSIUM 4306CB **Brief Summary**

ABBOTT

ACTIONS—Pharmacologically, TRANXENE (clorazepate dipotassium) has the characteristics of the benzodiazepines. It has depressant effects on the central nervous system. The primary metabolite, nordiazepam, quickly appears in the blood stream. The serum half-life is about 2 days. The drug is metabolized in the liver and excreted primarily in the urine.

INDICATIONS—TRANXENE is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

TRANXENE is indicated for the symptomatic relief of acute alcohol withdrawal.

The effectiveness of TRANXENE for long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

CONTRAINDICATIONS—TRANXENE is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS—TRANXENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on TRANXENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since TRANXENE has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, TRANXENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. TRANXENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

TRANXENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS—In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Patients on TRANXENE for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS—The side effect most frequently reported was drowsiness. Less commonly reported (in descending order of occurrence) were: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects included insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed.

DOSAGE AND ADMINISTRATION—

For symptomatic relief of anxiety:

TRANXENE is administered orally. The capsules may be given in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 15 to 60 mg. daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a daily dose of 7.5 to 15 mg.

TRANXENE capsules may also be administered as a single dose daily at bedtime; the recommended initial dose is 15 mg. After the initial dose, the response of the patient may require adjustment of subsequent dosage. Lower doses may be indicated in the elderly patient. Drowsiness may occur at the initiation of treatment and with dosage increment.

TRANXENE-SD tablets (22.5 mg.) may be administered as a single dose every 24 hours. This tablet is intended as an alternate dosage form for the convenience of patients stabilized on a dose of 7.5 mg. capsules three times a day. TRANXENE-SD tablets should not be used to initiate therapy.

TRANXENE-SD HALF STRENGTH tablets (11.25 mg.) may be administered as a single dose every 24 hours.

For symptomatic relief of acute alcohol withdrawal:

Recommended schedule: 1st 24 hours, 30 mg TRANXENE initially, followed by 30 to 60 mg in divided doses; 2nd 24 hours, 45 to 90 mg in divided doses; 3rd 24 hours, 22.5 to 45 mg in divided doses; 4th day, 15 to 30 mg in divided doses. Thereafter gradually reduce to 7.5 to 15 mg daily, and discontinue as soon as condition is stable. Maximum daily dose is 90 mg. Avoid excessive reductions in total drug on successive days.

DRUG INTERACTIONS—If TRANXENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that TRANXENE prolongs the sleeping time after hexobarbital or after ethyl alcohol, increases the inhibitory effects of chlorpromazine, but does not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If TRANXENE (clorazepate dipotassium) is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

MANAGEMENT OF OVERDOSAGE—Overdosage is usually manifested by varying degrees of CNS depression ranging from slight sedation to coma. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

There are no specific antidotes for the benzodiazepines. The treatment of overdosage should consist of the general measures employed in the management of overdosage of any CNS depressant. Gastric evacuation either by the induction of emesis, lavage, or both, should be performed immediately. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though rarely reported, may occur with large overdoses. In such cases the use of agents such as Levophed® (levarterenol) or Aramine® (metaraminol) should be considered.

While reports indicate that individuals have survived overdoses of TRANXENE as high as 450 to 675 mg., these doses are not necessarily an accurate indication of the amount of drug absorbed, since the time interval between ingestion and the institution of treatment was not always known. Sedation in varying degrees was the most common physiological manifestation of TRANXENE overdosage. Deep coma when it occurred was usually associated with the ingestion of other drugs in addition to TRANXENE.

CLINICAL PHARMACOLOGY—Studies in healthy men have shown that TRANXENE has depressant effects on the central nervous system. Prolonged administration of single daily doses as high as 120 mg. was without toxic effects. Abrupt cessation of high doses was followed in some patients by nervousness, insomnia, irritability, diarrhea, muscle aches, or memory impairment.

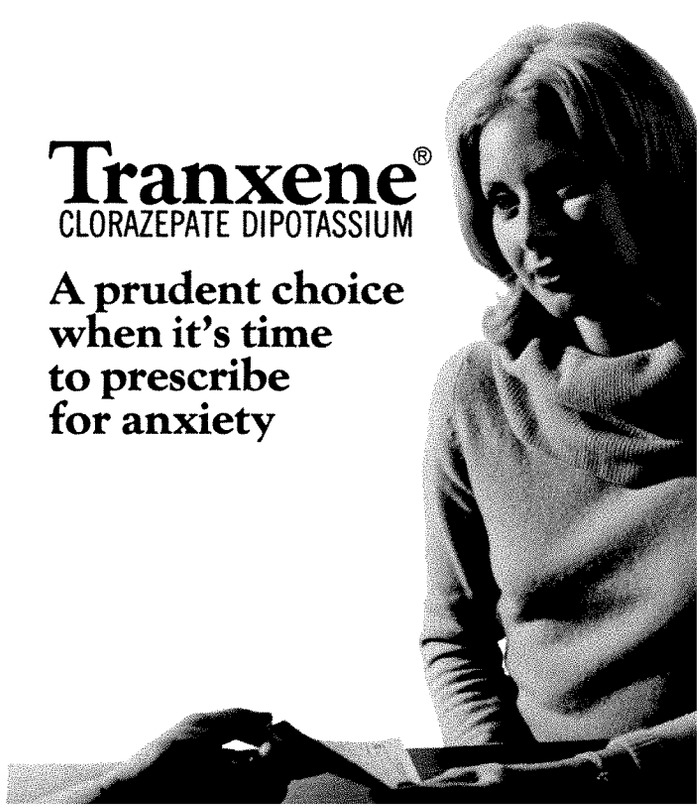
Absorption–Excretion:

After oral administration of TRANXENE, there is essentially no circulating parent drug. Nordiazepam, its primary metabolite, quickly appears in the blood stream. In 2 volunteers given 15 mg. (50 μC) of ^{14}C-TRANXENE, about 80% was recovered in the urine and feces within 10 days. Excretion was primarily in the urine with about 1% excreted per day on day 10.

HOW SUPPLIED—TRANXENE (clorazepate dipotassium) is supplied as capsules in three dosage strengths:

3.75 mg. capsules (gray with white cap) in bottles of 100 (NDC 0074-3417-13) and 500 (NDC 0074-3417-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3417-11).

7.5 mg. capsules (gray with maroon cap) in bottles of 100 (NDC 0074-3418-13) and 500 (NDC 0074-3418-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3418-11).



15 mg. capsules (all gray) in bottles of 100 (NDC 0074-3419-13) and 500 (NDC 0074-3419-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3419-11).

TRANXENE-SD single dose tablets are supplied in two dosage strengths:

TRANXENE-SD 22.5 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-2997-13).

TRANXENE-SD HALF STRENGTH 11.25 mg. tablets (blue-colored) in bottles of 100 (NDC 0074-2699-13).

7043191/R

A prudent prescription for today's anxious patient

A different tranquilizer. Times change. Today's patient has changed. And the physician's most prudent choice of therapy for anxious patients may also change. Thus if you are now thinking about changing your choice of minor tranquilizers, consider Tranxene.

A change of look. Tranxene is a physically distinctive change of therapy. It's very different in form and appearance from any other tranquilizers your patients have previously received or seen.

Greater versatility. Its added dosage options are different too. They permit not only conventional divided doses, but also convenient once-a-day regimens . . . including an ultrasimple single dose tablet (11.25 mg) especially suited to elderly patients.

Yet the same effectiveness. Prescribe with confidence. In numerous published studies involving hundreds of patients, Tranxene has been shown to be clinically equivalent to diazepam in treating anxiety.

Tranxene® 4306CB C IV
CLORAZEPATE DIPOTASSIUM

Maybe it's time?

In this issue

The Successful Professional Woman: On Being Married To One
By Theodore Nadelson and Leon Eisenberg

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

UNIVERSITY COLLEGE OF MEDICINE
LIBRARY

One of a series from
"The Many Faces of
STELAZINE®
brand of
TRIFLUOPERAZINE HCL
in Psychiatry."

Tiger Mask of the Nahuatl tribe
of Xitala, Guerrero, Mexico.
From the collection of
The Argel Galleries
Washington, D.C.
Reproduced with permission.

REMOVE THE MASK OF SCHIZOPHRENIC SYMPTOMS

'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY, AGITATION AND OTHER SCHIZOPHRENIC SYMPTOMS.

A FIRST CHOICE FOR THERAPY, 'STELAZINE' ALSO APPEARS TO HAVE AN ACTIVATING EFFECT WHICH IS ESPECIALLY USEFUL IN WITHDRAWN, APATHETIC OR DETACHED PATIENTS.

- EFFECTIVELY CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudoparkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only), 10 mg./ml.

TRIFLUOPERAZINE HCL

A FIRST CHOICE FOR THERAPY

The B24 III

UL LISTED

...a new generation of electroconvulsive therapy instrumentation from Medcraft.

Designed with patient and operator safety in mind, this new series of instrumentation meets the rigorous requirements for listing by Underwriters Laboratories — UL 544, Standards for Medical and Dental Equipment. The B24 III provides the physician with the ultimate in precision dosage levels. Consistancy of desired output level is assured with the following features:

- Line Voltage Compensation — allows compensation for fluctuations in incoming line voltages.
- Pre-programmed Voltage Selection — choice of eleven voltage levels from 70 volts to 170 volts.
- Automatic Treatment Timing — adjustable from 0.1 second to 1.0 second with or without Glissando.
- Current Output Indicators — visual assurance of current flow during treatment.

Exclusive Patient Test Module allows a complete systems integrity check of instrumentation prior to treatment. Clinical accuracy and dependability are assured by the use of 100% solid state circuitry. Double shielded transformer provides an additional margin of treatment safety. For ordering information, specifications and prices, write or call directly to:

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit 3 copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later. Annual meeting papers should not be submitted to the *Journal* until *after* the annual meeting.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

All communications about a manuscript should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; with other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, the copyright of all parts of the paper, including any illustrations, passes from the author to the *Journal*. Written permission to reprint material published in the *Journal* must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for this permission.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

SPECIFICATIONS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond paper. **All parts of the manuscript** (including case reports, footnotes, references, etc.) **should be double spaced,** with margins of 2½-3¾ cm (1-1½ inches) at the top, bottom, and both sides. Subheads should be inserted at reasonable intervals. All abbreviations should be explained. All measurements must be in metric units.

Length. All pages of the manuscript must be numbered, including references, tables, and figures. The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles: 3,800 words or the equivalent including references, tables, and figures (about 15 manuscript pages). Brief Communications: 2,500 words or the equivalent (about 10 manuscript pages); see stipulations above. Clinical and Research Reports: 1,000 words. 10 references, 1 table. Letters to the Editor: 500 words. Please write the total number of words and the number of tables and figures on the title page of the submitted material.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the coauthor who has been designated to assume responsibility for the paper and reprint requests. Authors named in the by-line should be limited to principal researchers and writers; other collaborators may be acknowledged in a footnote.

Precis. A brief precis (60–100 words for regular articles, 40–60 words for Brief Communications) is included at the beginning of each article. The author may prepare the precis or ask that the *Journal* staff prepare it.

References. References should be typed **double spaced** on a separate sheet of paper. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Tables and figures should be self-explanatory and should supplement, not duplicate, text. See recent issues of the *Journal* for general style.

Each table should be typed double spaced on a separate sheet attached at the end of the manuscript. Columns of like material should read down, not across.

One complete set of figures, in the form of glossy prints, should be submitted. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Graphs should be finished drawings not requiring further artwork. Authors are urged to engage professional assistance in the preparation of figures and may be charged for any further artwork that must be done in the editorial office.

AUTHORS CORRECTIONS

After the paper has been scheduled for publication, the edited manuscript will be sent to the first-named author for corrections and answers to queries. Prompt return is necessary. If an author expects to be away from his office for a long period of time after being notified of the acceptance of his paper, he should inform the *Journal* office or arrange with a coauthor to assume responsibility for the paper. Galley proofs will not be sent to authors.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article. Requests from others to order reprints should be directed to the APA Publications Services Division; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

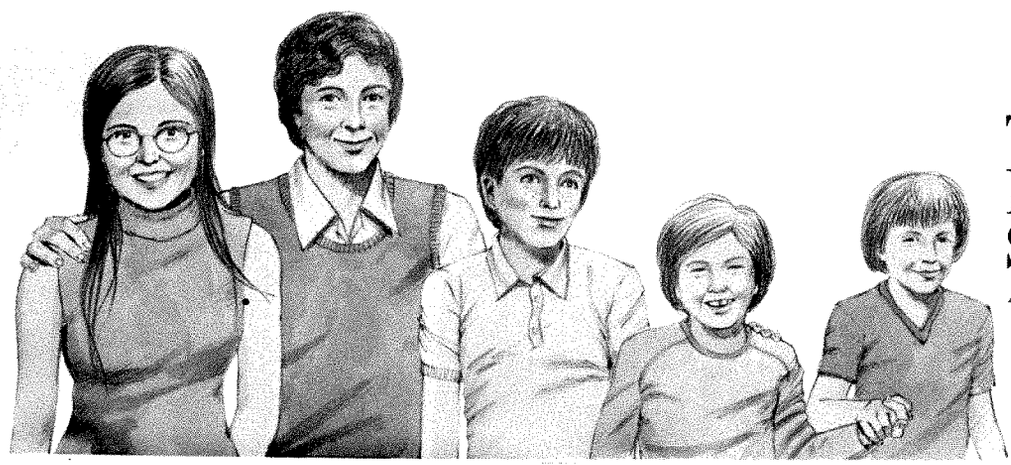
Flexibility is our forte: The Brown Schools

Because we maintain great flexibility at all three of our treatment centers, each resident follows an individualized plan of treatment, training, education and care prescribed for that resident alone.

And we believe that residential treatment conducted in this highly individualized manner still is the most effective treatment for many. Our large, experienced staff is skilled in the treatment of children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.



Our three treatment centers are geographically separated to provide the appropriate residential milieu, yet close enough that residents benefit from the comprehensive training and expertise of the entire staff. All three are psychiatrically oriented, so that we are prepared to treat emotional disturbance in persons of any intellectual capacity and of any age.

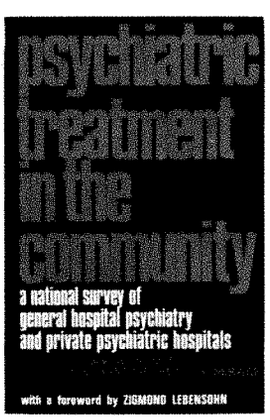
The November 1977 issue of

The American Journal of Psychiatry

will feature



- **The Neurobiological Origins of Psychoanalytic Dream Theory**
  By Robert W. McCarley and J. Allan Hobson

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

Hallucinations and delusions rapidly controlled

Trapped by unrealistic perceptions...

...and terrified by his hallucinations and delusions on admission. Because Navane (thiothixene) is particularly effective in controlling these symptoms and their resulting suspiciousness and anxiety, it can provide the essential first step toward restoring stabilization and facilitating the development of purposeful activity. Extensive clinical data and widespread experience confirm the effectiveness of Navane in rapidly controlling such typical psychotic behavior on admission.

Long-term therapy is facilitated...

...because Navane offers an unsurpassed safety record among effective neuroleptic agents, permitting continuing control of symptoms of psychoses such as hallucinations and delusions. Like other antipsychotic agents, extrapyramidal symptoms may occur, but are readily controlled through dosage adjustments or antiparkinsonian agents. Cardiovascular effects such as hypotension, and hepatic or hematopoietic effects rarely occur and are generally mild and transient, with no jaundice or agranulocytosis reported to date.

An effective first step towards discharge...

Navane®

(thiothixene) (thiothixene HCl)

Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. Concentrate 5 mg./ml.—Intramuscular 2 mg./ml.

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

ROERIG Pfizer

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor elevating action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg. of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

Anthropological and Cross-Cultural Themes in Mental Health

An Annotated Bibliography, 1925-1974
Armando R. Favazza and Mary Oman.

Knowledge of the themes common to the disciplines of psychiatry and anthropology can make a valuable contribution to their interface.

Favazza and Oman surveyed the literature of medicine and related fields to compile this annotated bibliography. The introduction explains the two disciplines' interaction and provides a brief history of the trends most evident in the fifty years covered. Tables enumerating various journals and subject matter give an objective view of the field of cultural psychiatry. More than 3600 entries make up the bibliography; they are arranged chronologically with two extensive author/subject indexes included.

The course will consist of daily sessions, Monday through Saturday, from 9:00 a.m. to 12:00 noon and from 2:00 p.m. to 5:00 p.m. Most of the 12 half-day sessions will treat a discrete topic from several points of view. The last one and one-half days will be devoted entirely to child neurology.

While designed primarily for neurologists, child neurologists and neurosurgeons, consideration of recent advances and pertinent basic material will make the presentations useful to internists, psychiatrists, pediatricians and generalists.

ADULT NEUROLOGY, 25 hours, Category 1, covering Epilepsy, Metabolic Problems, Neuro-ophthalmology, Neurological Advances, Diagnostic Techniques, Central Neurotransmitter Substances, CT Scanning, Pain and Neuroimmunology.

CHILD NEUROLOGY, 8 hours, Category 1, Neurocutaneous Syndromes, Cerebral Neoplasia in Childhood, Childhood Autoimmune Syndromes, the Precarious Fetal Position — Effect of Noxious Agents, Movement Disorders in Childhood, Common and Uncommon Neuromuscular Syndromes in Childhood.

Registrations accepted for either program or a combined 6-day course of 33 hours, Category 1.

For the complete program and registration information, contact:
Division of Continuing Medical Education, University of Miami School of Medicine, P. O. Box 520875, Miami, FL 33152.

Neurobiology Books

Cellular Basis of Behavior

An Introduction to Behavioral Neurobiology

Eric R. Kandel, Columbia University

Winner of the

Lester N. Hofheimer Prize for Research

Presented by the American Psychiatric Association

Lucy G. Moses Prize for Research in Basic Neurology

Presented by Columbia University

Eric R. Kandel has written a comprehensive overview of the principles of cell biology underlying behavior and learning. The *Cellular Basis of Behavior* is based on his conviction that cellular neurobiology and psychology are two aspects of a unified study, and that solutions to problems in the study of behavior will require their combined use.

Each topic is introduced in historical context and illustrated in detail, while allowing the reader to trace the roots of contemporary research and become familiar with experimental set-ups, the nature of the data produced, and how this data is interpreted. Dr. Kandel uses the experimental studies of the ophistobranch mollusc *Aplysia californica* to delineate neurobiological principles common to all animals. An extensive bibliography of recent work in the field of neurobiology is also included.

1976, 727 pp., 328 illus., cloth: $45.00, paper: $19.95

Introduction to Nervous Systems

Theodore H. Bullock, University of California, San Diego

With the Collaboration of

Richard Orkand, University of Pennsylvania, and

Alan D. Grinnell, The University of California, Los Angeles

This new introduction to neurobiology emphasizes the *organization* of nervous systems—the relationships and transformations among cells and groups of cells that form an integrated system for information processing and control.

Introduction to Nervous Systems begins with a series of chapters that introduce readers to the essential anatomical and biophysical features of nerve cells and tissues. Subsequent chapters consider the functional integration of the nervous system at all levels, from the neuronal to the behavioral. A full chapter is devoted to the developmental aspects and plasticity of the individual nervous system and another to a comparative survey of nervous systems throughout the animal kingdom—from medusa to man. The text includes a comprehensive glossary.

1977, 559 pp., 435 illus., cloth: $27.00, paper: $17.00

LIBRIUM®
(chlordiazepoxide HCl)
5 mg, 10 mg, 25 mg capsules

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported.

***Usage in Pregnancy:* Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

ROCHE

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

A CONSISTENT PATTERN OF PATIENT RESPONSE

Because psychotherapy holds so many variables, predictability of patient response to adjunctively administered medications is a much-sought objective. The consistency of patient response to Librium® (chlordiazepoxide HCl) therefore makes it a good choice when clinically significant anxiety interferes with therapy.

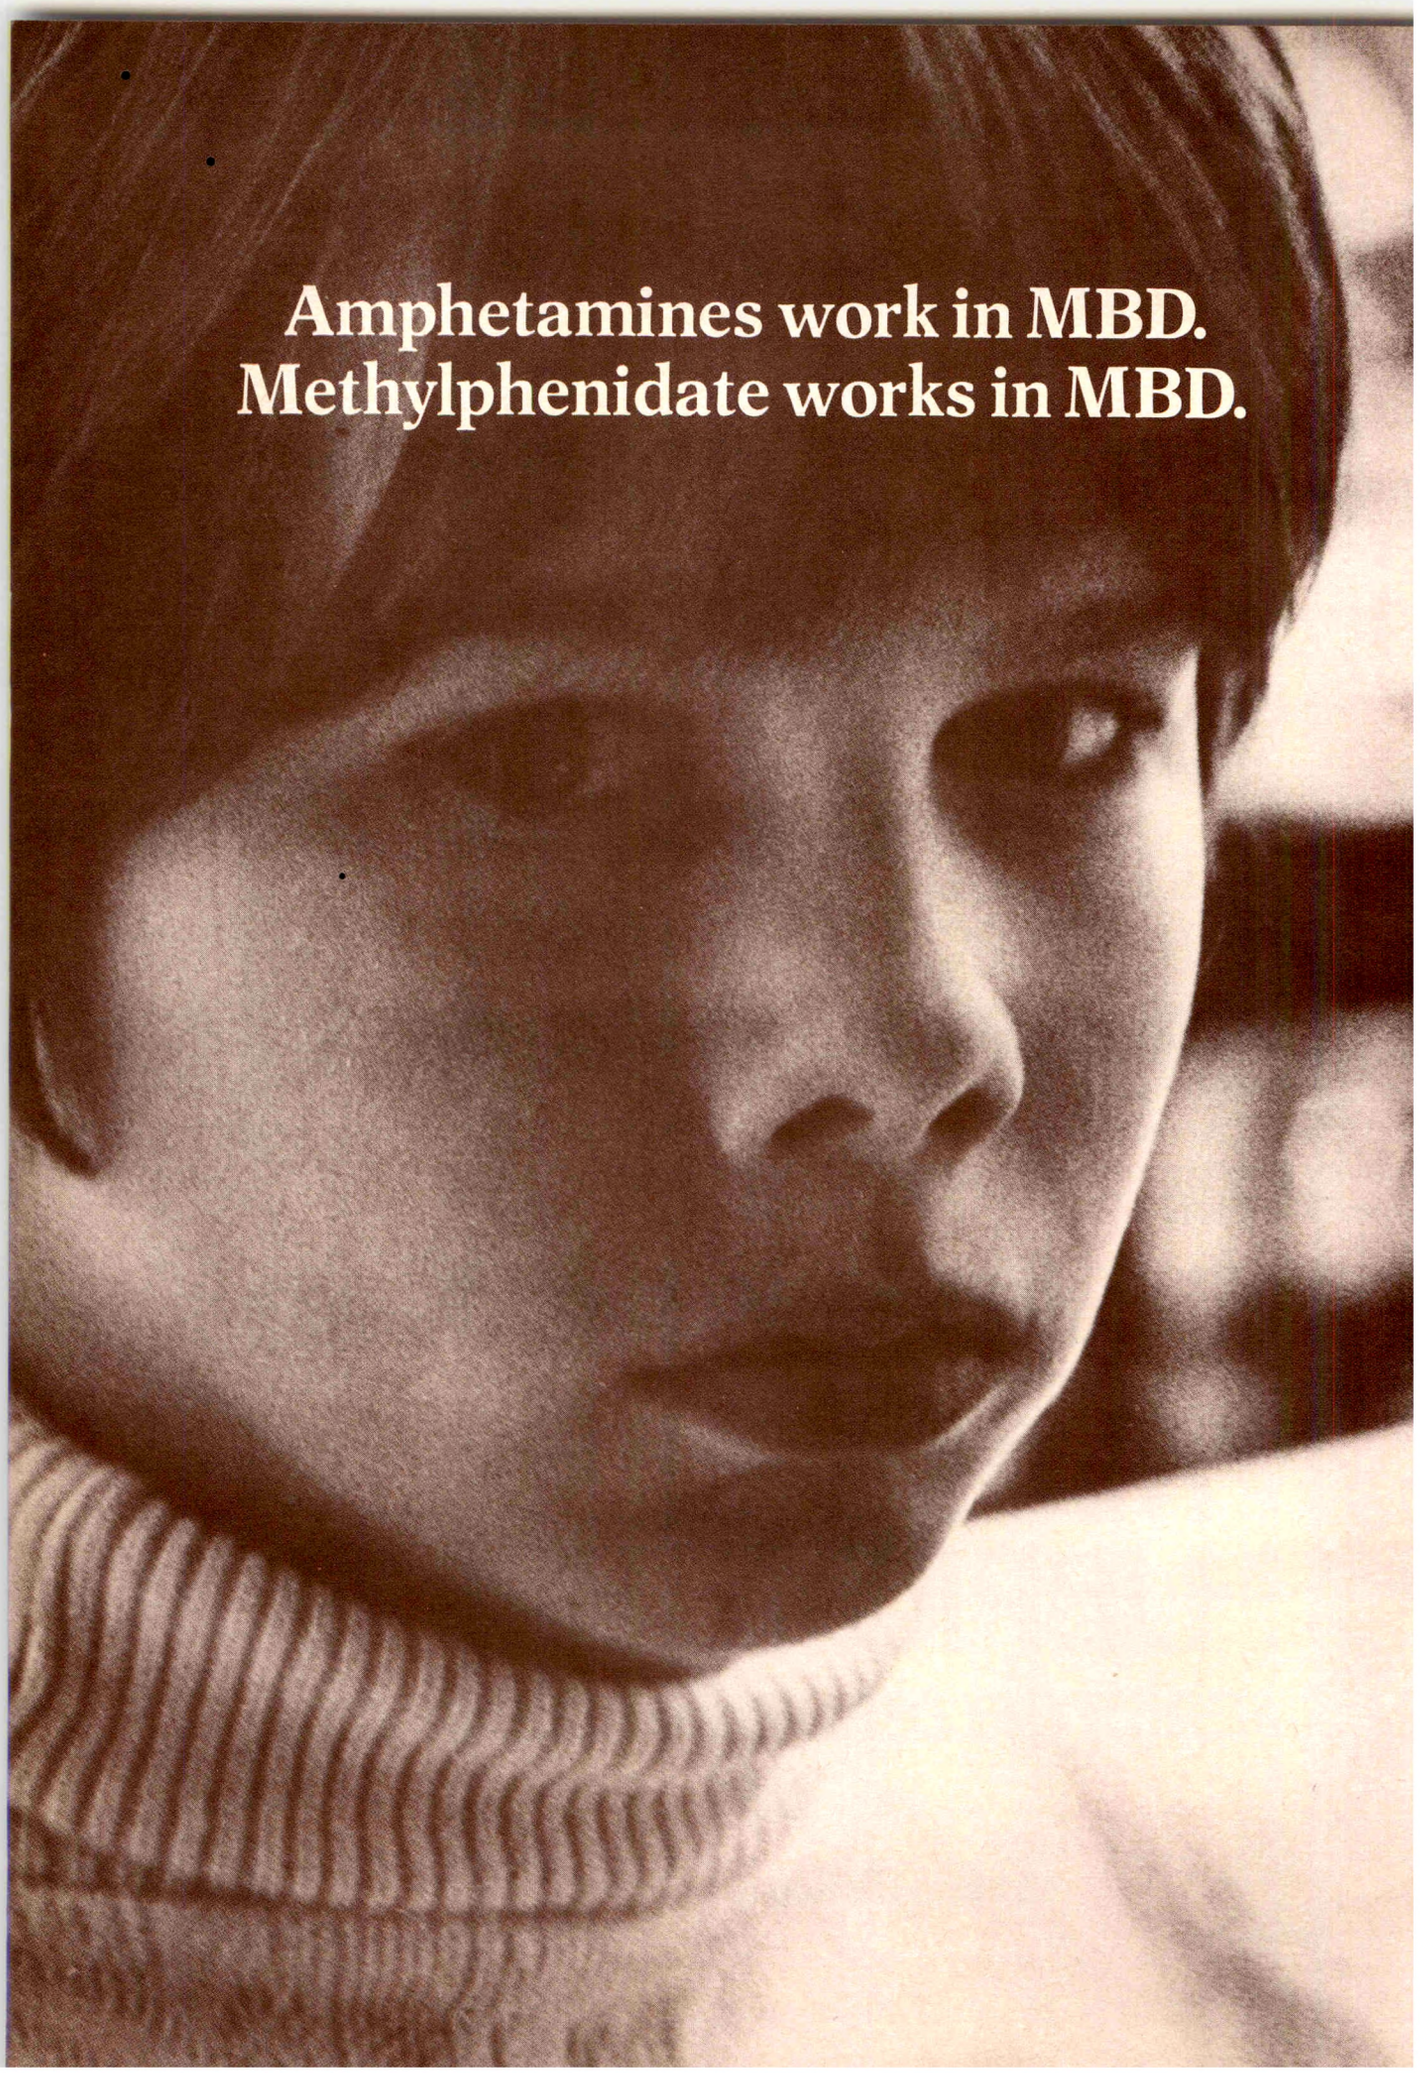
In order to tailor the regimen to the patient's response, flexibility in prescribing is essential. Through individualizing your patient's dosage of Librium, you can provide maximum beneficial calming effects with minimal side effects (the most common are dose-related and thus largely avoidable).

Moreover, Librium infrequently interferes with mental acuity. However, as with all CNS-acting drugs, patients should be cautioned against driving and hazardous activities requiring complete mental alertness.

With Librium you can rely on specific antianxiety action, probably confirmed by your own experience.

THAT'S WHAT MAKES LIBRIUM® LIBRIUM®

IV



chlordiazepoxide HCl/Roche

THE ANXIETY-SPECIFIC

ROCHE

Please see summary of product information on opposite page.

Amphetamines work in MBD.
Methylphenidate works in MBD.

Then why Cylert® for MBD?

(pemoline)

Because Cylert offers a lot:

- Once-a-day dosage at home
- Elimination of mid-day school dose and need for school personnel supervision
- Avoids ups and downs of drug action brought about by multiple daily dosage
- Control of medication by the parent
- A chewable dosage form
- Less physician paper work (Cylert is in schedule IV)
- Safety and efficacy proven in extensive clinical studies*

*Copy of the Cylert Monograph available to Physicians on written request.

Dosage and administration

Cylert is administered as a single oral dose each morning.

The recommended starting dose is 37.5 mg/day. This daily dose should be gradually increased by 18.75 mg at one week intervals until the desired clinical response is obtained. The effective daily dose for most patients will range from 56.25 to 75 mg. The maximum recommended daily dose of pemoline is 112.5 mg.

Clinical improvement with Cylert is gradual. Using the recommended schedule of dosage titration, significant benefit may not be evident until the third or fourth week of drug administration. Drug administration should be interrupted occasionally (once or twice a year) to determine if behavioral symptoms are sufficient to require continued therapy.

When not to use medication

Cylert should not be used for (and will not be effective in) simple cases of overactivity in school age children.

Neither should it be used in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

The physician should rely on a complete history of the child and a thorough description of symptoms from both parents and teacher before postulating a diagnosis of MBD.

ABBOTT

Please see next page for Prescribing Information.

7083202 R1

Cylert and Cylert Chewable Tablets

(pemoline)

Prescribing Information

Description: Cylert (pemoline) is a central nervous system stimulant. Pemoline is structurally dissimilar to the amphetamines and methylphenidate.

It is an oxazolidine compound and is chemically identified as 2-amino-5-phenyl-2-oxazolin-4-one.

Pemoline is a white, tasteless, odorless powder, relatively insoluble (less than 1 mg./ml.) in water, chloroform, ether, acetone, and benzene; its solubility in 95% ethyl alcohol is 2.2 mg./ml.

Cylert (pemoline) is supplied as tablets for oral administration.

Clinical Pharmacology: Cylert (pemoline) has a pharmacological activity similar to that of other known central nervous system stimulants; however, it has minimal sympathomimetic effects. Although studies indicate that pemoline may act in animals through dopaminergic mechanisms, the exact mechanism and site of action of the drug in man is not known.

The serum half-life of pemoline is approximately 12 hours. Peak serum levels of the drug occur within 2 to 4 hours after ingestion of a single dose. Multiple dose studies in adults at several dose levels indicate that steady state is reached in approximately 2 to 3 days.

Metabolites of pemoline include pemoline conjugate, pemoline dione, mandelic acid, and unidentified polar compounds. Cylert is excreted primarily by the kidneys; approximately 75% of an oral dose is recovered in the urine within 24 hours. Approximately 43% of pemoline is excreted unchanged.

Cylert (pemoline) has a gradual onset of action in children with minimal brain dysfunction. Using the recommended schedule of dosage titration, significant clinical benefit may not be evident until the third or fourth week of drug administration.

Indications: *MINIMAL BRAIN DYSFUNCTION IN CHILDREN*—as adjunctive therapy to other remedial measures (psychological, educational, social).

Special Diagnostic Considerations: The cause of minimal brain dysfunction (MBD) is unknown. Diagnosis of MBD involves the use of medical, psychological, educational, and social tools, since no single diagnostic test is adequate.

MBD is characterized by chronic moderate to severe hyperactivity, short attention span, distractibility, emotional lability, and impulsivity. Nonlocalizing (soft) neurological signs, learning disability, and abnormal EEG may or may not be present. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. In the primary therapy of MBD, appropriate educational placement is essential and psychosocial intervention is generally necessary. When these measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

Contraindications: Cylert (pemoline) is contraindicated in patients with known hypersensitivity or idiosyncrasy to the drug. (See ADVERSE REACTIONS.)

Warnings: Cylert is not recommended for children less than 6 years of age since its safety and efficacy in this age group have not been established.

Sufficient data on the safety and the efficacy of the long-term use of Cylert in children with minimal brain dysfunction are not yet available.

A temporary suppression of the predicted growth rate (weight and/or height gain) has been reported for children receiving long-term stimulant therapy. A definite causal relationship between stimulant drugs and this finding has not been established.

Precautions: Liver function tests should be performed periodically during therapy with Cylert. The drug should be discontinued if abnormalities are revealed and confirmed by follow-up tests. (See ADVERSE REACTIONS regarding reports of abnormal liver function tests and jaundice.)

Cylert should be administered with caution to patients with significantly impaired hepatic or renal function.

The interaction of Cylert with other drugs has not been studied in humans. Patients who are receiving Cylert concurrently with other drugs, especially drugs with CNS activity, should be monitored carefully.

Cylert failed to demonstrate a potential for self-administration in primates. However, the pharmacologic similarity of pemoline to other psychostimulants with known dependence liability suggests that psychological and/or physical dependence might also occur with Cylert. There have been isolated reports of transient psychotic symptoms occurring in adults following the long-term misuse of excessive oral doses of pemoline. Cylert should be given with caution to emotionally unstable patients who may increase the dosage on their own initiative.

Usage during Pregnancy and Lactation: The safety of Cylert (pemoline) for use during pregnancy and lactation has not been established.

Fertility, reproduction, and teratology studies were conducted in laboratory animals. Pemoline, in doses of 18.75 or 37.5 mg./kg./day, had no effect on the fertility of male or female rats. The drug, when given to pregnant rats (from gestation day 15 through weaning) and to rabbits (from gestation days 6-18) at these same dosage levels, produced no teratogenic or embryotoxic effects, and had no effect on the viability of the young at birth. However, increased incidences of stillbirths and cannabilization were observed when pemoline was given to rats at these dosage levels, beginning 14 days prior to conception.

Adverse Reactions: Insomnia is the most frequently reported side effect of Cylert; it usually occurs early in therapy, prior to an optimum therapeutic response. In the majority of cases it is transient in nature or responds to a reduction in dosage.

Anorexia with weight loss may occur during the first weeks of therapy. In the majority of cases it is transient in nature; weight gain usually resumes within three to six months.

Stomach ache, skin rashes, increased irritability, mild depression, nausea, dizziness, headache, drowsiness, and hallucinations have been reported.

Elevations of SGOT, SGPT, and serum LDH have occurred in patients taking Cylert, usually after several months of therapy. These effects appear to be reversible upon withdrawal of the drug, and are thought to be manifestations of a delayed hypersensitivity reaction. There have also been a few reports of jaundice occurring in patients taking Cylert; a causal relationship between the drug and this clinical finding has not been established.

There have been reports of dyskinetic movements of the lips, face, and extremities occurring with the use of Cylert. Convulsive seizures have also been reported. A definite causal relationship between Cylert and these reactions has not been established.

Mild adverse reactions appearing early during the course of treatment with Cylert often remit with continuing therapy. If adverse reactions are of a significant or protracted nature, dosage should be reduced or the drug discontinued.

Overdosage: Signs and symptoms of acute Cylert overdosage may include agitation, restlessness, hallucinations, tachycardia. The treatment for an acute overdosage of pemoline is essentially the same as that for an overdosage of any CNS stimulant. Management is primarily symptomatic and may include induction of emesis or gastric lavage, sedation, and other appropriate supportive measures.

Results of preliminary studies in dogs indicate that extracorporeal hemodialysis may be useful in the management of Cylert overdosage; forced diuresis and peritoneal dialysis appear to be of little value.

Dosage and Administration: Cylert (pemoline) is administered as a single oral dose each morning.

The recommended starting dose is 37.5 mg./day. This daily dose should be gradually increased by 18.75 mg. at one week intervals until the desired clinical response is obtained. The effective daily dose for most patients will range from 56.25 to 75 mg. The maximum recommended daily dose of pemoline is 112.5 mg.

Clinical improvement with Cylert is gradual. Using the recommended schedule of dosage titration, significant benefit may not be evident until the third or fourth week of drug administration. Drug administration should be interrupted occasionally (once or twice a year) to determine if behavioral symptoms are sufficient to require continued therapy.

How Supplied: Cylert (pemoline) is supplied as monogrammed, grooved tablets in three dosage strengths:

18.75 mg. tablets (yellow-colored) in bottles of 100 (NDC 0074-6025-13)

37.5 mg. tablets (orange-colored) in bottles of 100 (NDC 0074-6057-13)

75 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-6073-13)

Cylert Chewable is supplied as monogrammed, grooved tablets in one dosage strength:

37.5 mg. tablets (orange-colored) in bottles of 100 (NDC 0074-6088-13)

MANUAL OF PSYCHIATRIC PEER REVIEW

by the Peer Review Committee of the American Psychiatric Association, Donald G. Langsley, M.D., Chairperson in cooperation with the Joint Task Force on Diagnostic Criteria for Analyzability of the American Psychoanalytic Association, William Offenkrantz, M.D., Chairperson, and the Peer Review Committee of the American Academy of Child Psychiatry. Larry B. Silver, M.D., Chairperson.

"This Manual provides a set of guidelines for district branches of APA and their peer review committees which should be adapted and modified in terms of local criteria, standards, and practices. The guidelines are not intended to be hard and fast rules. They are screening criteria, and not regulations to control practice. They are so designed that they can be utilized by non-physicians to identify those cases that can profitably be reviewed by psychiatrists serving on peer review committees. This document should be viewed as transitional, subject to revision as experience is gained, and continually updated in response to advances in psychiatric knowledge and changes in patterns of practice. . . . The application of these standards, and refinement through experience must rest with the peer review committees of district branches. . . . It should help them to move ahead in the development of a peer review for American psychiatry."

Robert W. Gibson, M.D.
President

Part I titled PSYCHIATRIC PEER REVIEW contains sections on Basic Relationships and Responsibilities, Appointment of Peer Review Committees, Funding, Operations and Procedures, Medical Care Evaluation Studies, Appeals Processes, Special Problems, Confidentiality, Educational Aspects, Medical Ethics, Advocacy, Interdisciplinary Aspects, with Appendices on Model Screening Format for Inpatient Treatment for Alcoholism, Model Screening Format for Outpatient Treatment, Sample Form for Requesting Extension of Office Treatment, Claims Review Guidelines Suggestions, APA Position Papers on Peer Review, Bibliography.

Part II titled PSYCHOANALYTIC PEER REVIEW has sections on Steps in Peer Review for Psychoanalysis, Guidelines for Model Criteria Sets, Pilot Application of Guidelines for Model Criteria Sets, Sample Peer Review Form, Sample data from Pilot Applications of Guidelines, and Glossary of Terms Used.

Part III titled PEER REVIEW AND CHILD PSYCHIATRY contains sections of Special Considerations, Legal Rights of Children, Issue of Confidentiality, Conclusions, References, and Appendices on Model Screen Criteria Format for Intermediate Care, for Acute Care in a Short Stay Facilities, and for Partial Hospitalization, Outpatient Diagnostic Evaluation Procedures, and Outpatient Treatment for Children and Adolescents.

Published by the American Psychiatric Association, Washington, D.C., September 1976. 114 pages. Spiral binding. Single copies, $6.00. For orders of 10 or more, $5.00 per copy.

From the Sleep Research Laboratory: Dalmane® (flurazepam HCl) proved the most effective hypnotic over 14 nights...[1]

For those patients who need it, Dalmane (flurazepam HCl) alone provides continued effectiveness[2,3]

Since insomnia is often transient and intermittent, the prolonged administration of a hypnotic is generally not necessary or recommended. But for those patients whose insomnia is a chronic problem, the continued effectiveness of Dalmane is a decided benefit. Even at the end of a 28-night medication period, patients with chronic insomnia were falling asleep faster, spending less time awake during the night, and sleeping substantially longer on Dalmane 30 mg *h.s.* than on baseline placebo nights (average results). This effectiveness was proved[2] and confirmed[3] in two independent sleep research studies using a new 47-night protocol. When similarly evaluated, pentobarbital was ineffective at the end of two weeks.[2]

TOTAL SLEEP TIME (MEAN)[3]
(5 patients with insomnia)

*Significantly increased over baseline placebo ($p < .05$).

14 consecutive nights:
3 in sleep laboratory, 8 at home,
3 in sleep laboratory

...and now, the only one proved effective over 28 nights.[2,3]

In previous studies,[1] chloral hydrate and glutethimide lost most or all effectiveness

In fact, continued effectiveness for both inducing and maintaining sleep over 14 consecutive nights[1] has long been an exclusive benefit of Dalmane. No other available sleep agent, including chloral hydrate or glutethimide,[1] has been able to demonstrate such effectiveness in the sleep research laboratory.

The safety record of Dalmane (flurazepam HCl) is well established

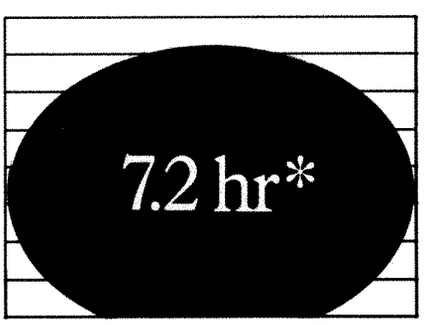
Dalmane is relatively safe and well tolerated. Prolonged administration is not generally necessary, but if used repeatedly, periodic blood counts and liver and kidney function tests should be performed.

Dalmane®
(flurazepam HCl)

relatively safe... no need to increase dosage

ROCHE

28 consecutive nights:
3 in sleep laboratory, 7 at home,
4 in sleep laboratory, 10 at home,
4 in sleep laboratory[3]



Please see following page for a summary of product information.

1,5,7,14,28 nights... as needed, the effectiveness of Dalmane® one *h.s.* (flurazepam HCl) C IV meets the challenge of insomnia

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

- **Patients fall asleep rapidly, sleep longer on a single *h.s.* dose**
- **Nighttime awakenings and time spent awake are reduced**
- **Effectiveness maintained without dosage increase from night to night**
- **Patients generally awaken refreshed; morning "hangover" is infrequent**

TOTAL SLEEP TIME (OVERALL MEAN)[3]
(5 patients with insomnia)

Dalmane (flurazepam HCl)
nights 1-3, 12-14, 26-28

*Significantly increased over baseline placebo ($p < .05$).

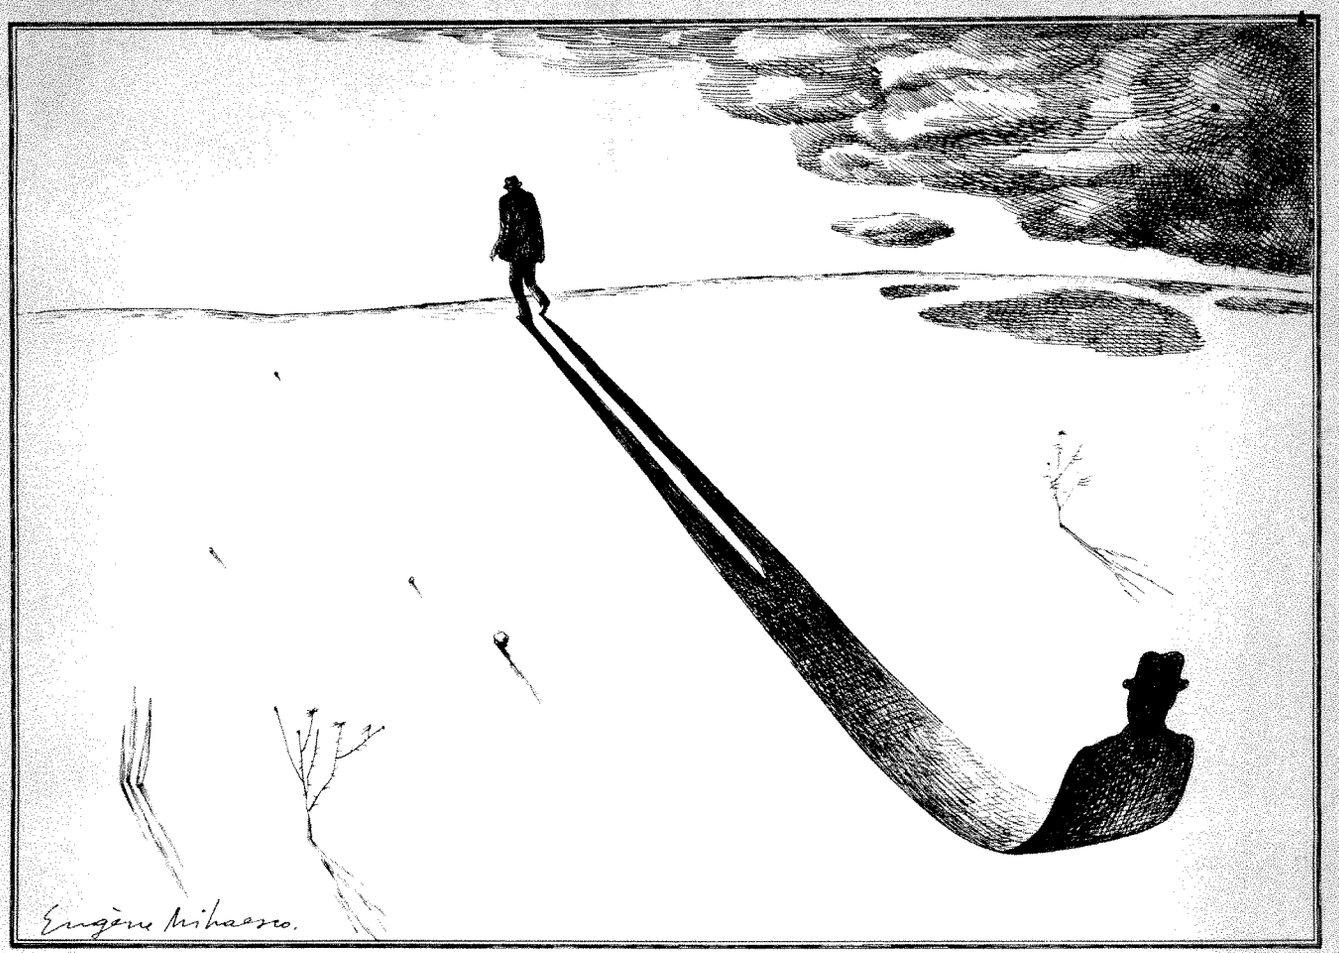
3. Dement WC, *et al*: Long-term effectiveness of flurazepam 30 mg *h.s.* on chronic insomniacs. Presented at the 15th annual meeting of the Association for Psychophysiological Study of Sleep, Edinburgh, Scotland, Jun 30-Jul 4, 1975



Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:
Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.
Contraindications: Known hypersensitivity to flurazepam HCl.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).

***Usage in Pregnancy:* Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane (flurazepam HCl), a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.
Precautions: In elderly and debilitated, limit initial dosage to 15 mg to preclude oversedation, dizziness and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.
Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.
Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.
Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

ROCHE

ROCHE LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

"I'm just a shadow of what I used to be."

That is what depressed individuals may feel is the substance of their being. There is no pleasure, no joy – nothing grows – and in the cold shadow of depression their activities are inhibited, while initiative may be eroded or destroyed. The tragedy is that they can see that others are able to live on the brighter side but they, themselves, cannot reach it on their own.

Your experience in treating depression, and Tofranil-**PM** can help light the way.

Tofranil-**PM**®
imipramine **pamoate**

Geigy

Unsurpassed effectiveness among tricyclics in relieving symptoms of anxious depression.

Before prescribing Tofranil-PM, please review a summary of the prescribing information on the back of this page.

Tofranil-PM®
imipramine **pamoate**

Geigy

As anxiety, agitation, sleep disturbances, and other depressive symptoms are relieved, mood and motivation may be markedly improved.

Patients are usually alert and capable of functioning at more normal levels of behavior.

Tofranil-PM encourages patient compliance because one capsule lasts from bedtime to bedtime.

Good results are usually seen at the starting dose of one 75-mg capsule h.s.

For many patients, dosage can be safely increased to 150 mg daily.

As with all tricyclics, sedation may occur. Please caution patients against driving or operating dangerous machinery.

Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg of imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;

—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;

—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;

—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;

—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

The American Psychiatric Association announces publication of two volumes reporting the Conference on Education of Psychiatrists

held at Lake of the Ozarks, Missouri, June 9-15, 1975. Organized by the A.P.A. in cooperation with the American Academy of Child Psychiatry, the American Association of Chairmen of Departments of Psychiatry, and the American Association of Directors of Psychiatric Residency Training.

1. PSYCHIATRIC EDUCATION: PROLOGUE TO THE 1980's, Library Bound, 544 pages, $15.00.

This is a substantive, highly readable, report of the Conference, written by Anne H. Rosenfeld with an Editorial Board comprising: Ewald W. Busse, M.D., Chairperson of the Conference, Walter E. Barton, M.D., Bernard Holland, M.D., Donna Norris, M.D., Melvin Sabshin, M.D., Jeanne Spurlock, M.D., and Robert L. Robinson, M.A. (Staff Consultant).

The volume contains ten chapters covering the topical structure of the Conference: Goals and Values; Competence, Evaluation, and Quality Control; The Resident; Faculty; Educational Methods: Means in the Service of Ends; The Program Environment; Research; The Economics of Residency Training; Psychiatry in Its Social Context; and Retrospect and Prospect. It also contains nine appendices describing the organization of the Conference and its participants, together with selected model programs and related informational materials of value.

2. THE WORKING PAPERS OF THE 1975 CONFERENCE ON EDUCATION OF PSYCHIATRISTS Paper bound, 432 pages, $12.50.

Sixty two leading psychiatric educators served on seven preparatory commissions, one for each of seven topic areas, and prepared advance working papers as a basis for Conference deliberations. The topics and Commission Chairpersons were: Social Issues and Needs (James N. Sussex, M.D.); Goals and Objectives (Morton F. Reiser, M.D.); The Resident (David R. Hawkins, M.D.); Content, Methodology, Faculty and Environment (Milton Greenblatt, M.D.); Research (Daniel X. Freedman, M.D.); Economics (Herzl Spiro, M.D.); Evaluation and Quality Control (Eric Pfeiffer, M.D.). The Chairpersons, together with the Conference Chairperson, served as the Editorial Board for this volume.

Papers commenting on the reports of the commissions, published here for the first time, were presented at the Conference by Melvin Sabshin, M.D., Eugene B. Brody, M.D., Jeanne Spurlock, M.D., Jack R. Ewalt, M.D., Robert J. Stoller, M.D., James R. Comer, M.D., and Bernard Holland, M.D.

"Now Andy's classmates laugh

with him, not at him"

Today, direct coaching in appropriate social interaction, role playing, and encounter techniques are being used to help hyperactive children overcome disruptive social behavior patterns that often cause them to become objects of ridicule to their peers.

Ritalin, when indicated, can also play a useful role in this respect, as improving social interaction in the MBD child often involves reducing hyperactivity. Indeed, as one investigator[1] has reported, with Ritalin therapy, the MBD child can be less aggressive, less impulsive, and better able to interact with his peers. Other studies also report improved social behavior of MBD children on Ritalin.[2,3]

A drug of choice when treatment of MBD is indicated,[4,5] controlled studies and clinical experience have demonstrated the ability of Ritalin to effectively reduce hyperactivity,[1,2] distractibility,[1,3] and disorganized behavior[1,3,6-8] in the MBD child.

And these symptomatic improvements achieved with Ritalin often result in the child being more responsive to the nonpharmacological measures of the MBD management team.[8]

Although side effects – insomnia and appetite loss – are occasionally seen with Ritalin, they are less frequent or severe than with dextroamphetamine.[4,10]

Therapy with Ritalin should be undertaken only after a medical diagnosis of MBD has been made. Dosage should be periodically interrupted. Often these interruptions reveal some "stabilization" in the child's behavior even without medication. In some MBD children they permit a reduction in dosage and eventual discontinuance of drug therapy.

Ritalin...Only when medication is indicated

Ritalin® (II)
(methylphenidate)
An effective member of the MBD management team

C I B A

Ritalin®
(methylphenidate)
Only when medication is indicated

Ritalin® hydrochloride
(methylphenidate hydrochloride)
TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Symptoms of visual disturbances have been encountered in rare cases. Difficulties with accommodation and blurring of vision have been reported.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over).

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-Pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

Dual Problem: marked agitation with depression

...a common problem in psychiatric practice.

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please see last page of this advertisement.

Dual-action TRIAVIL®

containing perphenazine and amitriptyline HCl

Marked agitation accompanying depression is a common problem in psychiatric practice, a problem often requiring dual-action therapy to effectively cope with both components of the disorder. TRIAVIL 4-25 helps treat both. A formulation particularly suited to psychiatric practice when higher doses are required, TRIAVIL 4-25 affords the psychiatrist the opportunity to treat marked agitation—each tablet containing 4 mg of the tranquilizer, perphenazine—while helping to relieve the coexisting depression with 25 mg of the tricyclic antidepressant, amitriptyline HCl.

helps treat both the marked agitation and the depression

An antidepressant alone may be adequate when the accompanying anxiety is mild, but dual-action TRIAVIL should prove more appropriate when the anxiety or agitation (accompanying depression) is moderate or severe.

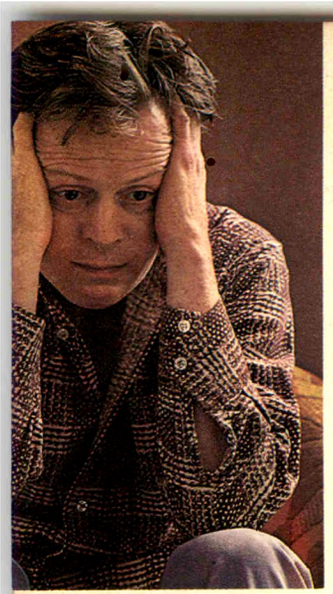
The four formulations of TRIAVIL permit the psychiatrist to treat a relatively broad spectrum of depressed patients who manifest symptoms ranging from moderate anxiety to severe agitation, and allow for individualized dosage adjustment.

The advantages of dual-action TRIAVIL in psychiatric practice.

With TRIAVIL, as anxiety or agitation with depression is relieved, the patient may become more accessible and cooperative. Many symptoms such as insomnia, fatigue, anorexia, and functional G.I. complaints are frequently alleviated; symptomatic relief may enable the patient to function more effectively in his daily activities, and the psychotherapeutic process itself may be aided.

TRIAVIL simplifies therapy; encourages compliance.

A single tablet encourages patients to take medication properly and reduces the risk of dosage confusion and error. Cost of therapy to the patient is usually less than when the components are prescribed individually. To date, clinical evaluations of TRIAVIL have revealed no undesirable reactions peculiar to the combination.



Treatment with TRIAVIL– a balanced view.

TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. It is not recommended in children or during pregnancy. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please see following page.

DUAL-ACTION Triavil®

containing perphenazine and amitriptyline HCl

for moderate to severe anxiety or agitation and depression

Available:
TRIAVIL® 2-25: Each tablet contains 2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains 2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains 4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains 4 mg perphenazine and 10 mg amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisi hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism have been reported and can usually be controlled by the concomitant use o effective antiparkinsonian drugs and/or by reduction in dosage, but som times persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy o may occur after drug therapy with phenothiazines and related agents ha been discontinued. The risk appears to be greater in elderly patients on hig dose therapy, especially females. Symptoms are persistent and in som patients appear to be irreversible. The syndrome is characterized by rhyt mical involuntary movements of the tongue, face, mouth, or jaw. Involu tary movements of the extremities sometimes occur. There is no know treatment for tardive dyskinesia; antiparkinsonism agents usually do not all viate the symptoms. It is advised that all antipsychotic agents be discontin ued if the above symptoms appear. If treatment is reinstituted, or dosage o the particular drug increased, or another drug substituted, the syndrome ma be masked. Fine vermicular movements of the tongue may be an early sig of the syndrome. The full-blown syndrome may not develop if medication stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythem urticaria, eczema, up to exfoliative dermatitis); other allergic reaction (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions) peripheral edema; reversed epinephrine effect; hyperglycemia; endocrin disturbances (lactation, galactorrhea, gynecomastia, disturbances of me strual cycle); altered cerebrospinal fluid proteins; paradoxical excitemen hypertension, hypotension, tachycardia, and ECG abnormalities (quinidin like effect); reactivation of psychotic processes; catatonic-like states; aut nomic reactions, such as dry mouth or salivation, headache, anorexi nausea, vomiting, constipation, obstipation, urinary frequency or inco tinence, blurred vision, nasal congestion, and a change in pulse rate; othe adverse reactions reported with various phenothiazine compounds, but n with perphenazine, include grand mal convulsions, cerebral edema, pol phagia, pigmentary retinopathy, photophobia, skin pigmentation, and failur of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (panc topenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinoph lia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after lon term administration of some phenothiazines. Although it has not bee reported in patients receiving TRIAVIL, the possibility that it might occu should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia hav also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for thi drug, but which have occurred with other pharmacologically similar tricycli antidepressant drugs and must be considered when amitriptyline is admini tered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromu cular:* Confusional states; disturbed concentration; disorientation; delusions hallucinations; excitement; anxiety; restlessness; insomnia; nightmares numbness, tingling, and paresthesias of the extremities; peripheral neur pathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (ant diuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred visio disturbance of accommodation; increased intraocular pressure; constipatio paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Ski rash; urticaria; photosensitization; edema of face and tongue. *Hematologic* Bone marrow depression including agranulocytosis; leukopenia; eosinoph lia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric di tress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; paroti swelling; black tongue. Rarely hepatitis (including altered liver function an jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male breast enlargement and galactorrhea in the female; increased or decrease libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness fatigue; headache; weight gain or loss; increased perspiration; urinar frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrup cessation after prolonged administration may produce nausea, headache, an malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosag should be admitted to a hospital as soon as possible. Treatment is sympt matic and supportive. However, the intravenous administration of 1–3 m of physostigmine salicylate is reported to reverse the symptoms of tricycli antidepressant poisoning. Because physostigmine is rapidly metabolized, th dosage of physostigmine should be repeated as required particularly if lif threatening signs such as arrhythmias, convulsions, and deep coma recur c persist after the initial dosage of physostigmine. On this basis, in sever overdosage with perphenazine-amitriptyline combinations, symptomati treatment of central anticholinergic effects with physostigmine salicylat should be considered.

NOW FROM SANDOZ

For the treatment of depression

PAMELOR®

(nortriptyline HCl) NF

25mg. Capsules

Provides 2 important benefits for both patients and clinicians.

- PAMELOR® begins to improve sleep patterns within a week.
- PAMELOR® allows patients to remain calm yet alert.

For Brief Summary please see following page.

NOW FROM SANDOZ

PAMELOR®
(nortriptyline HCl) NF
25 mg. Capsules

The antidepressant with 2 important clinical benefits

PAMELOR® begins to improve sleep patterns within a week

- PAMELOR® helps relieve the sleep problems that accompany depression: difficulty in falling asleep, restless sleep, and early-morning awakening. An improved pattern of sleep begins to appear in some patients within the first week of therapy.
- Overall improvement is often observed by the end of the second week. Maximum improvement with Pamelor®, as with other antidepressants, may require a longer period of therapy, particularly in severe depressive illnesses.

PAMELOR® allows patients to remain calm yet alert

- Helps improve depressed mood with a low level of stimulatory effect.
- PAMELOR® also has a mild calming action to help relieve the anxiety and tension that are often symptoms of depression. Because PAMELOR® rarely causes excessive drowsiness, patients are more alert and better able to function. Nevertheless, they should be cautioned about driving or operating machinery.

Indications: For relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Hypersensitivity. Should not be given concomitantly with MAO inhibitors or within 2 weeks of the use of this drug since hyperpyretic crises, severe convulsions, and fatalities have occurred when similar tricyclic antidepressants were used in such combinations. Cross-sensitivity with other dibenzazepines is a possibility. Contraindicated during acute recovery period after myocardial infarction.

Warnings: Use with caution in patients with cardiovascular disease because of tendency to produce sinus tachycardia and prolong conduction time. Myocardial infarction, arrhythmia, and strokes have occurred. May block antihypertensive action of guanethidine and similar agents. Because of anticholinergic activity, use cautiously in patients with glaucoma or a history of urinary retention. Patients with a history of seizures should be followed closely because the drug is known to lower the convulsive threshold. Great care is required for hyperthyroid patients and those taking thyroid medication because of possible development of cardiac arrhythmia. Caution patients about possibility of impaired mental and/or physical ability to operate a motor vehicle or dangerous machinery. Response to alcoholic beverages may be exaggerated and may lead to suicidal attempts. Safe use during pregnancy, lactation, and women of childbearing potential has not been established and the drug should not be given unless clinical situation warrants potential risk. Not recommended for use in children.

Precautions: Psychotic symptoms may be exacerbated in schizophrenic patients. Increased anxiety and agitation may occur in overactive or agitated patients. Manic-depressive patients may experience shift to manic phase. Hostility may be aroused. Concomitant administration of reserpine may produce a "stimulating" effect. Watch for possible epileptiform seizures during treatment. Use cautiously with anticholinergic or sympathomimetic drugs. Concurrent electroconvulsive therapy may increase hazards associated with nortriptyline HCl. When possible, discontinue drug several days prior to surgery. Potentially suicidal patients require supervision and protective measures during therapy. Prescriptions should be limited to the least possible quantity. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: The pharmacologic similarities among the tricyclic antidepressant drugs require that each of the following reactions be considered when nortriptyline is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia, panic, nightmares; hypomania; exacerbation of psychosis.

Neurologic: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alteration in EEG patterns; tinnitus.

Anticholinergic: Dry mouth and rarely, associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with other tricyclic drugs.

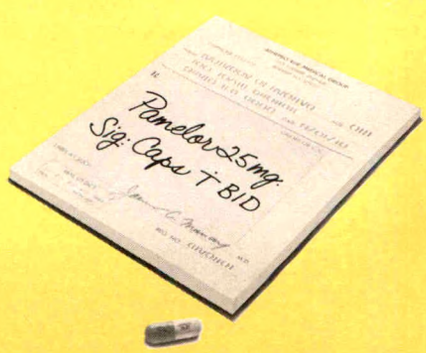
Hematologic: Bone-marrow depression, including agranulocytosis; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black-tongue.

Endocrine: Gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness, fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though these are not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.



Dosage and Administration: *Usual adult dose*—25 mg. three or four times daily; dosage should begin at a low level and increase as required. *Elderly and Adolescent:* 30 to 50 mg. per day, in divided doses. Doses above 100 mg. per day and use in children are not recommended. If a patient develops minor side effects, the dosage should be reduced. The drug should be discontinued promptly if adverse effects of a serious nature or allergic manifestations occur.

How Supplied: Capsules 10 mg. and 25 mg.; solution 10 mg./5 cc.

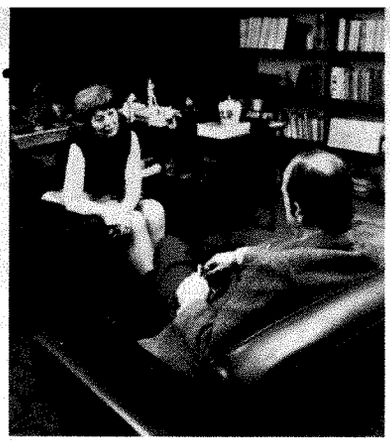
Haldol®
(haloperidol)
tablets/concentrate/injection

For prompt control with minimal risk of hypotension or oversedation

Highly effective in a wide range of psychotic symptoms[1-7]
such as hallucinations, delusions, suspiciousness, hostility, mania, psychomotor agitation, etc., in both acute and chronic disorders.

Helps keep patients functioning and avoid hospitalization.[1-3]
HALDOL haloperidol usually leaves most patients alert and responsive, able to function at work and at home without impairment, and more amenable to other therapeutic measures.

Permits aggressive titration to effective dosage levels[1,4]
up to 100 mg/day orally (with minimal risk of usual troublesome reactions) to achieve optimal response when patient is inadequately controlled at lower dosage...to help you rapidly control and stabilize new patients, promptly regain control during periods of exacerbation.



Common side effects easily controlled.[1,2,4]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Reduces risk of certain troublesome reactions.[1,2,4-6]
Transient hypotension occurs rarely and severe orthostatic hypotension has not been reported. Marked sedation is rare, although some instances of drowsiness have been reported. In addition, with chronic use, it is unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes...and has minimal effect on renal function.

Please turn page for information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions.

Important: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

Haldol®
(haloperidol)
tablets/concentrate/injection

For prompt control of psychotic symptoms with minimal risk of hypotension or oversedation

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

A tasteless, odorless, colorless liquid concentrate for better patient acceptability: 2 mg. per ml.

A rapid-acting injection for psychiatric emergencies: 5 mg. per ml., with 1.8 mg. methylparaben and 0.2 mg. propylparaben per ml., and lactic acid for pH adjustment to 3.4±0.2.

Contraindications: Severe depression, coma, CNS depression due to centrally-acting depressants, Parkinson's disease, hypersensitivity to the drug.

Warnings: ***Usage in Pregnancy:*** Safe use in pregnancy or in women likely to become pregnant has not been established; use only if benefit clearly justifies potential hazards. Infants should not be nursed during drug treatment.

Usage in Children: Safety and effectiveness not established; not recommended in pediatric age group.

Combined Use with Lithium: Patients receiving lithium plus haloperidol should be monitored closely for early evidence of neurological toxicity.

General: Bronchopneumonia, sometimes fatal, has followed use of major tranquilizers, including haloperidol. Prompt remedial therapy should be instituted if dehydration, hemoconcentration or reduced pulmonary ventilation occurs, especially in the elderly. Decreased serum cholesterol and/or cutaneous and ocular changes have been reported with chemically-related drugs, although not with haloperidol. Mental and/or physical abilities required for hazardous tasks or driving may be impaired. Alcohol should be avoided due to possible additive effects and hypotension.

Precautions: Administer cautiously to patients: (1) with severe cardiovascular disorders, due to the possibility of transient hypotension and/or precipitation of anginal pain (if a vasopressor is required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur); (2) receiving anticonvulsant medication since HALDOL haloperidol may lower the convulsive threshold; (3) with known allergies or a history of allergic reactions to drugs; (4) receiving anticoagulants. Concomitant antiparkinson medication, if required, may have to be continued after HALDOL haloperidol is discontinued because of different excretion rates; if both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson drugs, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used for mania in cyclic disorders, there may be a rapid mood swing to depression. Severe neurotoxicity may occur in patients with thyrotoxicosis receiving antipsychotic medication, including HALDOL haloperidol.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions:* Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which were usually mild to moderately severe and usually reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally, extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Antiparkinson drugs may be required. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Withdrawal Emergent Neurological Signs:* Abrupt discontinuation of short-term antipsychotic therapy is generally uneventful. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain cases these are indistinguishable from "Persistent Tardive Dyskinesia" except for duration. It is unknown whether gradual withdrawal will reduce the occurrence of these signs, but until further evidence is available haloperidol should be gradually withdrawn. *Persistent Tardive Dyskinesia:* Although rarely reported with HALDOL haloperidol, tardive dyskinesia may appear during or after long-term therapy. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and sometimes appear irreversible; there is no known effective treatment and all antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects:* Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports of mild, usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis; agranulocytosis rarely reported and only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice reported. ***Dermatologic Reactions:*** Maculopapular and acneiform reactions, isolated cases of photosensitivity, loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

The injectable form is intended only for acutely agitated psychotic patients with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. HALDOL tablets are manufactured by McNeil Laboratories Co., Dorado, Puerto Rico 00646. 5/77

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Single copy, $4.00; 10–49 copies; $3.80 each; 50 or more copies, $3.20 each.

SPECIAL OFFER: One copy of this book (regular price, $4.00) and one copy of **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (regular price, $6.50) for $8.50.

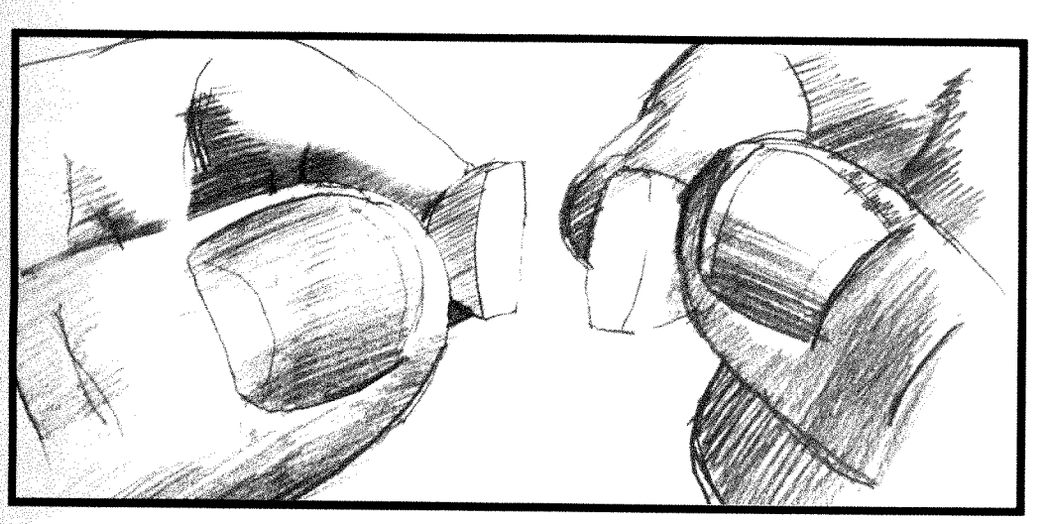
Why Endep® makes
with amitriptyline HC

Scored tablets h.s. enhance compliance and tolerability

Once you select the appropriate maintenance dose, you can prescribe a single tablet of Endep h.s. secure in the knowledge that you can adjust the dose by a half tablet without requiring the patient to obtain a new Rx. The simplicity of this h.s. schedule not only encourages compliance, but lessens the likelihood of anticholinergic and sedative side effects during daytime.

Scored tablets h.s. reduce confusion



Bedtime dosage means that the patient has only one dose of Endep to remember, thus minimizing possible confusion with other medications taken concomitantly. The built-in flexibility of the scored tablet permits half-strength dosage adjustments without confusing the patient with a new color or size of medication.

ROCHE

long-term maintenance more practical:

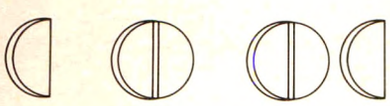
Scored tablets h.s. promote economy

The economy of Endep (amitriptyline HCl) is particularly evident during long-term maintenance therapy, when your patient is purchasing refills of the single strength you have prescribed. The h.s. schedule enables you to prescribe a single strength in place of a more expensive multiple-dose prescription. The scored tablet permits you to adjust the regimen without putting the patient through the expense of a new prescription fee, without wasting tablets and without necessitating the purchase of more costly multiple-dose refills.

Endep®

amitriptyline HCl / Roche

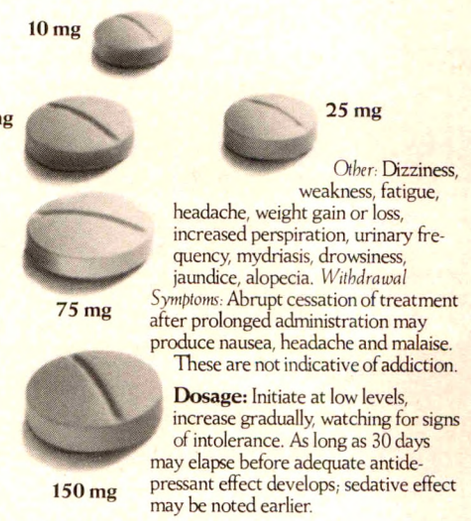
The half-strength advantage



Before prescribing, please see following page for a summary of product information.

Practicality is a fundamental fact about Endep®

amitriptyline HCl/Roche



Every tablet of Endep (amitriptyline HCl) is scored for precise, convenient adjustment of dosage.

Half-tablet adjustment of dosage does not require a new Rx.

Single daily *h.s.* dosage promotes compliance and economy.

Compliance with practical regimen promotes optimal response.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: To relieve symptoms of depression (notably endogenous depression) and depression accompanied by anxiety.

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle-closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Dosage: Initiate at low levels, increase gradually, watching for signs of intolerance. As long as 30 days may elapse before adequate antidepressant effect develops; sedative effect may be noted earlier.

Initial Adult Dosage: Outpatients—25 mg *t.i.d.*; may be increased to 150 mg/day. Add increased drug to afternoon and/or bedtime doses. Alternate—50 to 100 mg *h.s.*, gradually increasing *h.s.* dose up to 150 mg/day. Hospitalized Patients—Up to 100 mg/day; increase gradually to 200 mg if necessary. A few patients may require 300 mg/day.

Adolescent and Elderly Patients: In general, 10 mg *t.i.d.* with 20 mg *h.s.* may be satisfactory for those who do not tolerate higher doses.

Maintenance Dosage: With symptomatic improvement, reduce dosage to lowest amount that gives relief, usually 25 mg *b.i.d.* to *q.i.d.*, or 10 mg *q.i.d.* Continue maintenance therapy 3 months or longer to avoid relapse.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. IV administration of 1 to 3 mg physostigmine salicylate reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestations and treatment.

Supplied: 10-mg, 25-mg, 50-mg, 75-mg, 100-mg and 150-mg scored tablets—bottles of 100 and 500; Tel-E-Dose® packages of 100; Prescription Paks of 60 (10 mg, 25 mg and 50 mg) or 30 (75 mg, 100 mg and 150 mg), available singly and in trays of 10.

Just Published . . .

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

CASE SUMMARY SHEET

History:
Left school at 16. Good in math; poor reader. Youngest child (only son); two married sisters well adjusted. Father died six years ago; mother, two years ago. Patient attractive, precise in manner. Few friends, no girlfriend. Lives alone

Onset of current illness:
When customer questioned addition of grocery slip, patient became abusive, said he "didn't steal." Threw slip at customer; hit store manager; tried to break cash register. Police brought him to hospital

Diagnosis:
Acute schizophrenia

Treatment:
LOXITANE® C Loxapine Hydrochloride Oral Concentrate 50 mg stat then 20 mg q.i.d. increased over 3 weeks to 35 mg q.i.d. Psychotherapy twice weekly

Therapeutic course:
First week: Calmer, sometimes curses, not physically violent. Believes cash register is part of a "conspiracy" to discredit him. Facial tremors appeared which responded to antiparkinsonism medication

Second week: Delusions persist but less often expressed. Not verbally abusive. Cooperative with ward regimen. LOXITANE C 30 mg q.i.d.

Third week: Boasts he "figures" better than the cash register. No further delusions. Switched to LOXITANE® Loxapine Succinate Capsules 35 mg q.i.d.

Fourth week: Says "girls are messy, always leaving makeup around." Encouraged to discuss relationships with people. Likes the OT worker because she is "neat and tidy"

Fifth week: In therapy sessions, speaks of "loneliness" and "fear of making mistakes." Appears close to premorbid behavior. LOXITANE decreased 25 mg q.i.d., antiparkinsonism medication discontinued

Sixth week: Asked to see eldest sister. Patient asking about day passes

Follow-up:
Tenth week: Sister took patient out for the day. Patient pleased but has difficulty expressing emotion. Asked about leaving the hospital; not upset when told he is not ready yet. LOXITANE 20 mg t.i.d. and 10 mg h.s. Group therapy once weekly

*Not an actual patient. The collection of clinical data upon which this simulation is built illustrates the action of LOXITANE® Loxapine Succinate as reported in clinical studies.

Loxitane®
LOXAPINE Lederle SUCCINATE

For the symptoms that brought him there

Recommended Daily Dosage

Initial Dosage	MILD 10 mg b.i.d.	MODERATE 10 mg t.i.d. or q.i.d.	SEVERE 25 mg b.i.d.
First 7 to 10 Days	Increase dosage until psychotic symptoms are controlled Dosage should not exceed 250 mg/day Usual dosage during titration: 50 to 150 mg/day		
Maintenance Dosage	Adjust to lowest effective level Usual maintenance dosage: 60 to 100 mg/day Many patients are controlled with dosages as low as 20 to 60 mg/day		

Brief Summary

LOXITANE® Loxapine Succinate Capsules
OR
LOXITANE® C Loxapine Hydrochloride Oral Concentrate

Description: A dibenzoxazepine compound, representing a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines.

Indications: For the manifestations of schizophrenia. Loxapine has not been evaluated for the management of behavioral complications in mental retardation, and therefore cannot be recommended.

Contraindications: In comatose or severe, drug-induced depressed states (alcohol, barbiturates, narcotics, etc.); and in individuals with known hypersensitivity to the drug.

Warnings: In Pregnancy: Safe use during pregnancy or lactation has not been established; in pregnancy, nursing mothers, or women of child-bearing potential, weigh potential benefits against possible hazards to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from mid-pregnancy with doses of 0.6 and 1.8 mg./kg., doses which approximate the usual human dose but which are considerably below the maximum recommended human dose. **In Children:** Studies have not been performed in children; therefore this drug is not for use below the age of 16.

May impair mental and/or physical abilities, especially during the first few days of therapy; warn ambulatory patients about activities requiring alertness (e.g., operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

Precautions: Use with extreme caution in patients with history of convulsive disorders; seizures have been reported in epileptics receiving this drug at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy. Has an antiemetic effect in animals; this effect in man may mask signs of overdosage of toxic drugs and obscure conditions such as intestinal obstruction and brain tumor. Use with caution in patients with cardiovascular disease. Increased pulse rates in the majority of patients receiving antipsychotic doses and transient hypotension have been reported. In hypotension requiring vasopressor therapy, preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine. Possibility of ocular toxicity from loxapine cannot be excluded at this time, therefore observe carefully for pigmentary retinopathy and lenticular pigmentation (observed in some patients receiving certain other antipsychotic drugs for prolonged periods). Because of possible anticholinergic action, use with caution in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

Adverse Reactions: CNS: Adverse effects other than extrapyramidal, infrequent. Drowsiness, usually mild, may occur at beginning of therapy or when dosage is increased; usually subsiding with continued therapy. Incidence of sedation is less than that of certain aliphatic phenothiazines and slightly more than piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported. Extrapyramidal reactions during use of this drug have been reported frequently, often during the first few days of treatment. In most patients, these involve Parkinson-like symptoms such as tremor, rigidity, excessive salivation, masked facies, akathisia, usually not severe and controlled by dosage reduction or use of antiparkinson drugs in usual dosage. *Less frequent, but more severe:* Dystonias, including spasms of muscles of neck and face, tongue protrusion, oculogyric movement; dyskinesia in the form of choreo-athetoid movements. These sometimes require reduction or temporary withdrawal of drug dosage in addition to appropriate counteractive drugs. *Persistent Tardive Dyskinesia:* May appear in some patients on long-term therapy, or after therapy has been discontinued; the risk greater in the elderly, especially females, on high dosage. These symptoms, persistent and in some patients apparently irreversible, are characterized by rhythmical involuntary movement of tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements, sometimes accompanied by involuntary movements of extremities). No known effective treatment; discontinue all antipsychotic agents if these symptoms appear. The necessity to reinstitute treatment or increase dosage, or switch to a different antipsychotic agent, may mask syndrome. If medication is stopped when fine vermicular movements of the tongue occur, the syndrome may not develop. *Cardiovascular:* Tachycardia, hypotension, hypertension, lightheadedness, syncope. A few cases of EKG changes similar to those seen with phenothiazines have been reported, not known to be related to loxapine use. *Skin:* Dermatitis, edema (puffiness of face), pruritus, seborrhea. Possible photosensitivity and/or phototoxicity; skin rashes of uncertain etiology seen in a few patients during hot summer months. *Anticholinergic:* Dry mouth, nasal congestion, constipation, blurred vision—more likely to occur with concomitant use of antiparkinson agents. *Other:* Nausea, vomiting, weight gain or loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, polydipsia. Rarely, galactorrhea and menstrual irregularity of uncertain etiology.

Dosage and Administration: Administered orally, usually in 2 to 4 divided doses a day. Adjust dosage to patient's need relative to severity of symptoms and history of response to antipsychotic drugs. Recommended initial dosage is 10 mg. b.i.d.; in severely disturbed patients up to 50 mg. daily. Increase dosage during first 7 to 10 days until psychotic symptoms are controlled. Usual therapeutic and maintenance range is 60 mg.-100 mg. daily. More than 250 mg. daily is not recommended. Maintenance dosage should be at lowest level to control symptoms; many patients have been maintained on 20 mg. to 60 mg. daily.

LOXITANE C Oral Concentrate should be mixed with orange and grapefruit juice shortly before administration. Use only enclosed calibrated dropper.

SANDOZ
SAN 6-640R

ANTIPSYCHOTIC EFFICACY... INFREQUENT EXTRAPYRAMIDAL SYMPTOMS

Antipsychotic medication should not interfere with the patient's ability to participate in your total therapeutic program. That is why Mellaril (thioridazine) is an excellent choice. It is highly effective, and although extrapyramidal symptoms are characteristic of this class of drug, with Mellaril (thioridazine) extrapyramidal stimulation—notably pseudoparkinsonism—is infrequent. Adding an antiparkinsonian agent—which can cause its own side effects—can usually be avoided.

Mellaril (thioridazine) is not habituating and usually does not cause euphoria or undue sedation. (But, warn patients about undertaking activities requiring complete mental alertness.) And Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

MELLARIL® (THIORIDAZINE)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP

©1977 Sandoz, Inc.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Successful Professional Woman: On Being Married To One

BY THEODORE NADELSON, M.D., AND LEON EISENBERG, M.D.

Femininity and professionalism traditionally have been regarded as incompatible. From their own experience and that of colleagues and patients, the authors argue that female personhood is enriched by professional commitment. In consequence, the woman with a career becomes a more stimulating spouse and parent. Problems of role differentiation and of time allocation stress the dual-career marriage, but coping with those stresses enhances personal growth and leads to a more rewarding marital relationship. The authors consider themselves the most fortunate of men.

FOOLS write papers that are autobiographical; wiser men confine their confessions to their analysts.[1] If further proof of folly be needed, note our temerity as men in daring to opine about the conditions of women's lives. Our hubris fairly invites criticism from colleagues, from readers, worse yet, from our wives. Clearly, we are not easily deterred. In our role as participant-observers in that most intense of relationships with successful women—being married to them—we insist on our right to something to say on the matter.

This essay is not based on generalizations from a sample of two. Our personal observations have been augmented by reflecting on the men we have known as friends, colleagues, and patients over our professional life-times. Preparing this paper offered us an opportunity for collaboratively taking stock, as friends, members of the same academic community, and fathers of children adolescent and older. We share one final perspective: we write in celebration of wives as well as marriages we consider hugely successful—which is not to say without problems to be resolved and tensions to be managed. And yet, for our investment in marriage, we have in return experienced interpersonal adventures of greater intensity than we had been able to imagine in the romantic dreams of our adolescence. Indeed, the most forceful realization from our common reminiscences is that fulfillment in marriage, much as in individual maturation, is enhanced by coping with and overcoming developmental crises.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Nadelson is Assistant Professor of Psychiatry and Dr. Eisenberg is Maude and Lillian Presley Professor of Psychiatry, Harvard Medical School, Boston, Mass. Address reprint requests to Dr. Nadelson at the Department of Psychiatry, Beth Israel Hospital, Boston, Mass. 02215.

[1]S. Freud, personal communication.

WHAT IS A "SUCCESSFUL WOMAN"?

The term "successful woman" highlights the ambiguity of the adjective "successful" when it modifies the noun "woman." Literally, it refers to success in professional (nonmarital) life. Associatively, it implies success in being a woman (i.e., being feminine) as well. The dual connotation underscores the double standard that is prevalent in our sexist society. For, in contrast, the term "successful man" would at once be understood to describe one who is outstanding in his work role rather than in his sex or paternal role (that is, a successful lover or father).

Traditionally, the status of a wife is ascribed rather than achieved; that is, it is derivative from the social position of her husband. Thus, in most studies that include social class as an important variable, the children of married women are assigned a place in the social hierarchy corresponding to their father's income, occupation, and education. Census inquiries into the occupation of "head of household" automatically report that of the husband, unless there is no husband present. It has been taken as a social given that when the marriage is intact, the male is the head of the household.

This definition has not changed despite the fact that half the women in this country are in the paid labor force, including 46% of those with children (1, 2). What had been a "deviant" role for women a half century ago has become the modal one. The tipping point has been reached; it will be the unpaid housewife, not the working wife, who will feel social pressure to justi-

fy her role (3). Many women work because they want to and derive important personal satisfactions from an expanded social network, from the sense of accomplishment, and from the independence that comes from generating an income. However, many work out of necessity in jobs they find distasteful, a description that applies equally well to much of the male labor force (4). If we recite the obvious, it is to highlight the contrast between the ordinary work of most women and men and the work our physician wives and we are privileged to do. Our reflections, therefore, are limited to marriages in which the wife has a commitment to a professional career (5). That commitment is evident from the high motivation necessary to master career tasks and from the importance of occupational achievement to personal satisfaction (6–8).

Success, like status, has both a public and a private meaning. At a public level, success can be measured by the applause of others, by income level, by position in an organizational hierarchy and, for women, by being one among the very few who have attained a given level. Thus, a woman who is an associate professor or a dean is, in an important sense, more successful than a man occupying the same position because there are so few like her. As psychiatrists know all too well, the private conviction of success is no simple correlate of public recognition. To generalize from the limited sample of perhaps 40 professional women we have known, the successful woman is more likely to doubt her own worth than her male counterpart. It is not that we do not know men who remain convinced of their own incompetence despite external acclaim, but that the syndrome does appear to be more prevalent in successful women.

OCCUPATIONAL HAZARDS FOR PROFESSIONAL WOMEN

One does not have far to search for the sources of this discontent. In all disparaged groups, negative attitudes toward one's reference group all too readily become internalized. To be a successful woman is to be dealt with as an exception, which serves to reinforce the concept of inherent group inferiority. The stereotypes of the professional woman almost always incorporate the dogma of her "mannishness" and physical unattractiveness. To be regarded as feminine continues to be important to most women. Indeed, compliments to women on their "brainiess" may evoke a need to be reassured that they are not ugly. The husband of the successful professional has a role that is in no sense unique in meeting his wife's need for reassurance of her worth as a person (just as he needs this from her), but it is one that he may fail to recognize because it may seem absurd that a woman so competent and so attractive should need to be told the obvious.

Furthermore, he often finds his wife asking him advice about professional matters in which her judgment is superior to his own. Occasionally, this is nothing more than a ploy to make husbands feel needed, and, for that, we acknowledge our gratitude. Most often, it is not advice that is being sought but support for her own judgment. She is moving in realms where few women have moved before her, and she may doubt her legitimacy in situations in which men take their authority for granted. When she sets out a major concept at a committee meeting, discussion proceeds as if she had been silent; in the summary at the meeting's end, her idea may be included but accredited to a male colleague or, at best, left unattributed. Moreover, she is more likely to experience open challenge and covert sabotage because she is a woman in an executive position. Both men and women are more likely to defer to the man who occupies the same role. An additional reason for the "home consultation" is no more complex than the failure of her prior socialization to prepare her to function in social roles of command.

SECULAR CHANGES IN DUAL-CAREER PATTERNS

The experience of the men and women of our generation includes an important time differential. The usual pattern has been one in which the husband's career has advanced without interruption while his wife has deferred her own for child bearing and rearing. We do not suggest that this should be so but point out that it has been the case. Although we may have contributed more to child care than most fathers, it must be acknowledged that we have cooperated—perhaps even conspired—with our wives to give them the dominant role in home building, a role that corresponded with both our expectations and theirs about task division within marriage. Whatever the reason, the husbands in our cohort have had their careers moderately well established before their wives wholeheartedly pursued their own. It therefore required less personal sacrifice from a position of accomplishment to support a junior professional on her way up than to defer ambition, and not merely convenience, for the sake of another. We were also better able to provide guidance, when it was wanted, simply on the basis of our greater experience. The challenge to narcissism is far greater when coequal sacrifice is demanded at the beginning of marriage. In the past, women have borne the burden of delay disproportionately. They are becoming less willing to do so. They are right and men will have to change.

ROLE STRAINS FOR THE HUSBAND

For many professional men, it is an unusual and sometimes disquieting experience to attend, in the role of spouse rather than primary guest, the social gatherings that originate from work relationships. Depending upon his skills in small talk, the husband may stand around uncomfortably amidst strangers who politely

inquire, without any real interest, just who he is and what he does, quite a change from being "somebody" by definition. This experience provides at least a taste of what wives quite regularly experience, although it is a considerably muted one. No man in our sample can recall being asked about where he shops, his favorite dishes, the schools the children attend or being told how lovely he looks. And there is the assumption that we *do* work, an uncommon state of affairs for our wives outside academic circles. Indeed, we must acknowledge that the social role of husband as spouse is not really symmetrical with that of the wife. The following anecdote conveys its flavor:

> L's wife had been appointed to a senior position in a university, a role that made her the only woman on its governing council. The council had completed its year's work with a two-day weekend meeting followed by a dinner for "members and their wives" according to the invitation, with L as the only male "wife" (later changed to "spouse," with some embarrassment on the part of the secretariat). Soon after he arrived at the reception, L was called aside by the presiding officer and asked to be the unannounced "mystery after-dinner speaker." L, who is never at a loss for words (as his wife, when pressed, will testify), readily agreed. He was introduced amid general merriment, told a few more or less funny jokes (which by his report brought down the house) and then proceeded to admonish the group, in his self-appointed role as spouse-person, in protest against the invasion of "our" domestic weekends by university demands. All was in good spirit and taken seriously by no one, including the speaker; work patterns at the university remain unchanged, very much like the response to President Carter's entreaty to government executives on the importance of family life.

Clearly, "husband as spouse" is a special and jovial role, precisely because it remains so atypical.

Considerably less amusing is the attitude of some men who are smugly ensconced in traditional marriages. Having heard that one is married to a woman of some prominence, they respond with such comments as: "She must be quite a handful" or, more crudely, "How do you take not being in charge?" or (as a backhanded compliment) "You must be something to be able to manage her." Generally, the remarks are accompanied by a quizzical look if not a smirk. The assumptions clearly are that the husband is hardly a man if he is not in charge and quite a man if he is and that, however competent or independent the wife, what she "really" wants, like Katarina in *The Taming of the Shrew*, is a man to dominate, if not to spank, her till she exclaim, "Such a duty as the subject owes the prince, even such a woman oweth to her husband" (V, ii, 155–159).

THE DIVISION OF LABOR: WORKER, EXECUTIVE, OR PARTNER?

The commonplace chores of domestic life challenge the "liberated" husband's nominal commitment to an egalitarian marriage (9). Even those who accept task sharing as the norm usually view their role as accepting assignments, with more or less cheer, but expect executive responsibility to be carried by the wife. Being scrupulous about doing half the physical work, much of it mindless, is not the same as doing half the real work. Worrying about what needs doing and planning ahead for it exact important costs.

Family executive functions, in our clinical experience, demand a sizable reverberating neuronal circuit, thus preempting major pathways and consuming inordinate amounts of metabolic energy. How else can one explain the common complaint of the married woman physician: that she falls asleep evenings over journals and books when her husband still seems wide awake? The double load of family responsibility and professional responsibility results in wildcat strikes by overworked cortical neurons. As one woman professor said to her equally distinguished husband, "How often do you suddenly think, in the midst of lecturing to a class, 'My God, we have no toilet paper! I'd better stop on the way home and pick some up.' " That couple decided, not without some anguish, to contract on alternate months for one and then the other to take full responsibility for the household, including shopping for, and cooking, meals for guests. At follow-up, 3 years later, the plan is working remarkably well; the husband now boasts, to the considerable discomfort of his male colleagues, of his success in his new role.

After a national meeting a number of years ago (at the beginning of the women's movement) one member of our sample had a rude encounter with his own feelings. He had been almost completely ignored by a gathering of women who were all very interested in speaking with his wife. She stayed too long, he thought, and afterward, during a discussion of where to go for dinner, he felt she was too demanding. His response was anger, barely contained. Unable to control himself, he suddenly burst forth, castigating her character as controlling. Subsequently, he realized the source of his feeling in competitiveness and jealousy. Magnanimously (or so he thought), he gave her the gift of saying that he realized he had been acting out anger related to wounded pride and self-esteem. She said, "Yes, I know."

He had expected, he said, that she would soothe his feelings and (consonant with the model of behavior for men and women) give him support for the strength he displayed in admitting that he was jealous. She would say, in the expected scenario, that, after all, "you are strong and I was wrong." That had been demonstrated by his understanding of the angry feelings that he had renounced by identifying them. When she only acknowledged that he was obviously jealous, giving him no reward for his tour de force of insight, his anger redoubled. In later years he realized that moment to be a turning point (with no turning back) in the relationship with his wife. Her position was not that of being a wife, mother, and guardian of the hearth acting "as if" she were a professional like him. His anger had been

continuous because he felt a challenge that crystallized at the very moment because she only reiterated that he was, in fact, angry and she would not remove the reasons for it by reassuring him of his dominance and her submission. The change in him occurred slowly, reluctantly, and creakingly. Now, he regards his life as a rich one; in fact, he reports that it is hard for him to imagine what it would be like to have a resolutely domestic wife.

Many males in professional couples come only slowly to the understanding that their wives really "mean it," i.e., truly consider professional activities the major endeavor in their lives. Often the *female* partners arrive at this position with the help of other women; it is our impression that they arrive at it less often with help from their husbands.

Some men we have spoken to still indicate that there are times when they feel annoyance or anger engendered by a wife whose professional duties bend the household out of shape. Even those husbands who are beyond expecting a well-run, tidy household often are irritated when clothes are not available for their children for a special event. There is often an expectation that the wife should control all aspects of such events, as illustrated by the following incident reported by one of our subjects (after assurance of confidentiality):

> When I made a trip to the cleaners because I remembered that my son was to take his first look at a new school and had no clean clothes, I felt very virtuous and I wore my virtue as an indictment against my wife. It is only in retrospect that I realized that she had set up the appointment for him at the school and that really, logically, we shared the responsibility for the clean clothes equally. Happily I realize it now without her reminding me—that's too embarrassing. Maybe the encounter with such embarrassment in the past is helping to extinguish my annoyance.

However, such reactions extinguish slowly because of long-standing, reinforced attitudes regarding women's and men's roles.

What is essential to a workable arrangement is a "good wife" for both spouses—the luxury of a competent and caring housekeeper who not only does the household tasks but helps in the planning. Someone has to keep tabs on the necessities that need replacement and to deal with the small army of repair- and trades-people. That such a person is difficult to find hardly needs mention. Those who do find one feel blessed.[2]

THE THEFT OF TIME

Time, a scarce commodity in the dual-career family, becomes layered with multiple meanings in the psychological transactions between parents and children. To recognize that the development of a child is a function of the amount and kind of care the child receives is not to assert that the care must be provided solely by the parents. Even when surrogates provide the major part of the care, parents continue to possess far greater salience for children than substitute caretakers (10). Yet, despite what we, as professionals, know to be true, we remain prone to feelings of guilt. Many of us are too readily manipulated when our children use the tactic of measuring our performance by conventional standards.

> Larry had asked his mother to come to his school's Christmas play in which he was to be one of the Wise Men. None of her careful explanations of why she could not come during office hours (his father was going to be out of town) consoled him. Later that night, she became so uncomfortable at the vision of her poor son as the only child without a parent present that she cancelled her appointments for the following morning. When she came to school, she found herself the only parent present!

This vignette exemplifies something that is less of a problem for our children than for us as parents because of our fantasies of parental omnipresence. Real mischief results when the child's inevitable complaints about being shortchanged (complaints which occur in every family) strike a resonant chord in a father who shares his child's expectation that mother should aways be there and who resents being called upon to share the responsibility. Child and father can play upon mother's guilt about her "deviant" role and keep her in a chronic state of discontent. For most of us, to the contrary, our greater role in nurturance, beyond the usual didactic and disciplinary functions, has yielded a bouquet of satisfactions our own fathers were denied or denied themselves.

Given the demands of an active professional life, the physician-mother has, on average, fewer hours in the week than the housewife to be with her children. That statement does not translate into what is commonly taken to be its equivalent: that the child is cheated of care. How time is spent is more important than how much time is spent, within wide limits. We underestimate what we give our children.

> Allen's mother overheard him talking to a schoolmate about their parents' occupations. Allen proudly explained that both his parents were psychiatrists who make unhappy people feel better. His companion had no difficulty in describing his father's occupation as an orthopedist who fixed broken bones but he said his mother "didn't do anything." Allen was unable to understand this and kept insisting that she must "do something." His friend finally blurted out: "I know what she does! She yells and hollers at me and talks on the telephone all day!" After his friend had gone home, Allen ran to his mother in the kitchen, embraced her, and said: "Am I *glad* you're a doctor!"

Still, it is an inescapable consequence of the clock that there is more room and more need for fathering, a substantial benefit for us as well as for our children, if

[2]We acknowledge our profound debt to our housekeepers, Mrs. Soares and Ms. Lyons, who unsung and unknown help make our full lives possible.

we are capable of responding effectively. For the loss in absolute time, the children have offsetting gains in the quality of the relationships they can have with both parents. For the girls, wider career horizons are present as tangible possibilities; for the boys, there is exposure to more egalitarian marital roles. They interact daily with a woman as well as a man who is a full participant in the human activities of the workplace and the homeplace. There is less risk for the child of becoming the sole source of parental satisfaction, with its attendant infantilization and impediments to autonomy. Children are expected to contribute more to the functioning of the household since chores must be parceled out. We acknowledge that we speak of potentialities rather than guarantees; competence as a parent is not a necessary consequence of competence as a professional. What we emphasize is, other things being equal, the countervailing virtues within a dual-career marriage that more than offset the constraints imposed by the competing demands on time (11).

One of the most important costs of the dual-career marriage is *time lost* to companionship, a nonsexist cost borne equally by both partners, although even here equality is more apparent than real. Clock time spent apart is by definition the same for both partners, but experienced time may be quite different. To the extent that women are socialized into roles more expressive than instrumental and into greater dependence on affectionate feedback for maintenance of self-esteem, there may be differential pricing in its personal cost. However, we suggest that this is offset by the way men are socialized so that they are less ready to have personal needs for attention displaced by their wives' career demands. However the calculus works out in a given marriage, the fact is that professional work is not contained within a 9:00–5:00, five-day week schedule. Evening and weekend hours are often invaded, in part by emergencies, participation in local meetings and lectures or conferences out of town, and in part by keeping up with the literature and preparing papers for professional journals. Home work is less preemptive than away work because it is carried out in a common residence, can be interrupted for a bit of conversation or an affectionate gesture, and is followed by sharing a common bed. Sleeping together at the least provides comforting companionship, even if in a comatose state, and at its best can lead to something very much better. Time away leaves one partner homebound, beset with all of the household and child-care chores, and feeling lonely, perhaps even abandoned. The more professionally ambitious the spouses are, the more togetherness will be invaded this way. Yet an irreducible minimum follows inevitably from a serious commitment to professionalism as opposed to part-time doctoring. With two partners involved, the effects are psychologically multiplicative rather than additive. The very best efforts to coordinate schedules still result in her being out on evenings when he is home or him out when she is otherwise unengaged. Moreover, if there are young children to be cared for, scheduling may have to be deliberately staggered.

The net effect is a very considerable loss for the marriage, particularly for the good rather than the bad one. The husband and wife who enjoy each other ache at being apart; when the two do not get on well, being apart may partially resolve tensions between them. The couples we know speak sadly of "passing like ships in the night." The wife or the husband may be unavailable just at the very time when the partner needs support. Weekends take on an extraordinary importance as just about the only opportunity for sustained conversation. Social activity, other than that connected with the workplace, tends to atrophy just because time together alone becomes so highly valued and others, even close friends, can be resented for intruding upon it.

It is a problem without a full solution. What each spouse loves in the other is a configuration that would not be the same without the work commitment. But the work commitment diminishes availability. One has less of what one wants. The cost comes with the benefit. Even though the cost cannot be eliminated, we emphasize the importance of containing it. As is the case with medical care, without systems of cost control, time costs will consume the gross marital product.

THE JOYS OF TIME

Despite ourselves and our intent, we find that we have focused on problems and their resolution rather than joys and satisfactions. This may stem, in part, from a medical preoccupation with pathophysiology even amidst general health and in part from masculine embarrassment at public acknowledgment of tenderness and love. Be all that as it may, it remains to us to voice the cascade of pleasures that flow from a wife who is a complete human being in her own right, a "total woman" if we may rescue a phrase from its perversion. We have wives who are intellectual companions as well as lovers, and who are better lovers because we share so much more. It is high privilege, indeed, to live with another who is impassioned and compassionate, a sympathetic listener and a font of fresh insights and understandings, a distiller of wisdom.

We have had—and continue to have—a quite extraordinary experience in marriage, not one we were perceptive enough to seek when we fell in love nor even one we welcomed fully when its depth first became manifest but one with unique meaning for our own growth: the experience of living with a complete woman. We had been socialized to expect less and to settle for the creature comforts that came with that acceptance. Along the way, we may have shown some lack of grace in surrendering the customary conveniences; yet in return we have been granted a love the richer and fuller for having its roots in mutual respect and growing maturity. That, we acknowledge, we owe to our wives. Had it not been for their capacity to insist on respect for their integrity, it is doubtful we

would have achieved what we now enjoy. Of course it was not unilateral; we claim our due for what we have fashioned together; but we know it would not have happened without what they brought us: gentle courage, soft strength, selfless individuality.

Our wives are our best friends. No, it is not because, as the conventional wisdom currently has it, friendship between men is difficult, at least for us as particular men. We have men to whom we are close, whose friendship we treasure, with whom we can share our private thoughts, hopes, and fears. It is that our wives are all that, and more. They do not replace friends or make them unnecessary. We continue to need, and be needed by, friends, both men and women. But our wives, our "successful professional women," are our lovers, our friends, and our comrades in loves and lives of high adventure.

We consider ourselves the most fortunate of men.

Asylums Revisited

BY ROGER PEELE, M.D., PAUL V. LUISADA, M.D., MARY JO LUCAS, DIANE RUDISELL, AND DEBRA TAYLOR

The authors revisited Erving Goffman's Asylum *(Saint Elizabeths Hospital) and found both the "institutionalization" and "secondary adjustment" phenomena he described 20 years ago. However, they question whether secondary adjustments necessarily follows institutionalization. They also express doubt that institutionalization should be condemned automatically and suggest that it may in fact be the approach of choice for some patients.*

TWENTY years ago, Erving Goffman did a year of field work at Saint Elizabeths Hospital. He said that his "immediate objective . . . was to try to learn about the social world of the hospital inmate, as this world is subjectively experienced by him." He continued,

> I started out in the role of an assistant to the athletic director, when pressed avowing to be a student of recreation and community life, and I passed the day with patients, avoiding sociable contact with the staff and the carrying of a key. I did not sleep in the wards, and the top hospital management knew what my aims were. (1, p. IX)

Parts of his study were published in the late 1950s. The book *Asylums*, which combined his observations of the mentally ill with social aspects of life in other types of institutions, was published in 1961.

Asylums has since become one of the most quoted books on the social aspects of mental illness. It not only spread the realization that institutions are inhumane when poorly funded but also nourished the idea that "institutionalism" or "institutionalitis" is a disease entity in itself that can be developed in the mental hospital and is, in fact, an intrinsic part of the institution, regardless of its staffing and accommodations. Goffman went one step further and suggested that medical and progressive institutions were more degrading than purely custodial ones (1, p. 150).

Other publications at about the same time (2–5), with different orientations, pointed out the social aspects of hospitals that might contribute to patients' behavior and problems in patient management. Together, these books helped create a climate of a need for change that had a tremendous impact on the thinking of the 1960s.

The need to improve the institutions that managed the mentally ill had been a recurrent theme in both public and professional domains for over a century; the call of the 1950s and 1960s was different in that it suggested abolishing the psychiatric hospital rather than improving it. Although the intent of Goffman's work was not to pronounce remedies, *Asylums* became a major resource for those who worked for reform and those who advocated abolition of institutions.

We will begin with the question of whether the setting Goffman visited has changed in the two decades since his stay and, if so, in what ways.

SAINT ELIZABETHS: A COMPARISON OF TWO PERIODS

Hospital statistics suggest that something is quite different at Saint Elizabeths now: the overall inpatient population has shrunk from over 7,000 to 2,700, and outpatient rolls have expanded from several hundred to 2,700. A third of the wards are sexually integrated, whereas men and women were completely segregated in 1956. All wards were closed wards then; now, one-fourth are open. At the time of Goffman's stay, all of the hospital was behind a wall or a fence; now, there is a major portion of the hospital that is not surrounded by a fence. Admissions have more than doubled and the number of deaths, which peaked in the year Goffman visited the hospital, is now less than a third of the 1956 figure. Although exact figures are not available, it is thought that admissions are younger now and the proportion admitted on a voluntary basis has moved from a few percent to about half. Median inpatient stays, which were then a number of months, are about three weeks. Still, none of these figures tell us whether the social phenomena Goffman saw have changed.

In an effort to examine the social phenomena from Goffman's point of view, three summer college students (M.J.L., D.R., D.T.) who were interested in

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Peele is Associate Clinical Professor of Psychiatry and Behavior Science, George Washington University, and Acting Superintendent, Saint Elizabeths Hospital, Washington, D.C. 20032, where Dr. Luisada is Staff Psychiatrist, Area D Community Mental Health Center, and Mses. Lucas, Rudisell, and Taylor are Research Assistants. Dr. Luisada is also Surgeon, U.S. Public Health Service.

The views presented herein do not reflect the opinions or policy of Saint Elizabeths Hospital, the U.S. Public Health Service, or George Washington University.

mental health studied Goffman's work in some detail and then visited some of the hospital wards to determine whether what he saw could still be seen.

A BRIEF REVIEW OF ASYLUMS

Goffman begins by describing a "total institution" as one "whose character is symbolized by the barrier to social intercourse with the outside and to departure that is often built right into the physical plant, such as locked doors, high walls," and so forth. Total institutions share the following characteristics:

> First, all aspects of life are conducted in the same place and under the same single authority. Second, each phase of the member's daily activity is carried on in the immediate company of a large batch of others [who are] required to do the same thing together. Third, all phases of the day's activities are tightly scheduled with . . . one leading . . . into the next. Finally, the various enforced activities are brought together into a single rational plan purportedly designed to fulfill the official aims of the institution. (1, pp 5–6)

Goffman next describes what he called the "moral career" of a mental patient, i.e., the process whereby a person with position, friends, and ties in the community is institutionalized and converted into an inmate whose social sphere is limited to his immediate hospital environment. The institutionalization process begins with a series of assaults on the recruit's self; these assaults strip the patient of his former identity. The patient is then inserted into the lowest rung of an all-embracing privilege system. Goffman asserted that although the stripping process and privilege system are rationalized as being in the patient's best interests on therapeutic grounds, the real purpose is to break his spirit and make him more manageable.

The process of stripping inmates of their identity involves such initiation rituals as trading personal clothes and belongings for hospital issue. The inmate undergoes mortifying procedures that consist of a series of assaults on his self-image. Private, personal activities go on public display; he must request permission for even the most minor activities that were purely volitional on the "outside," such as smoking, shaving, or going to the toilet.

With his prepatient identity in tatters, his outside community stripped away, and his life under constant surveillance, the inmate enters the privilege system, the bases of which are the house rules. Goffman observed that privileges were always reductions in the institution's degree of control over the patient's life; increased "freedom" was the reward for obeying the rules.

Goffman's major point concerned the phenomena he termed "secondary adjustments," which he saw as a direct result of institutionalization and as the hallmark of institutionalism. From the hospital's point of view, the stripping process and privilege system extricated the patient from his presumably pathological environment and introduced him to a therapeutic milieu. Goffman observed that rather than following this intended plan, patients acted as if their major concerns were to escape the hospital's pervasive control.

The inmate found a new identity in the ways he used to reduce the hospital's control over his life; these were the secondary adjustments, defined as "the habitual arrangements by which patients employ unauthorized means, or obtain unauthorized ends, or both." Patients varied in the types of secondary adjustments they made: some became professional errand-runners, using their time off the ward in the various "free places" on the grounds where there was no staff scrutiny. Others hired or were hired by fellow patients to perform services, forming quasi-business enterprises that assured an income independent of staff control. The major portion of the book is devoted to descriptions of the rich patient "underlife" at Saint Elizabeths Hospital—the aggregate of the secondary adjustments of the 7,000-plus inpatients.

Goffman finally considered that some secondary adjustments were overdetermined, i.e., were of no intrinsic value and were undertaken merely because they were forbidden. He saw secondary adjustments as placing a barrier between an individual and the social unit in which he is supposed to be participating, a "rejection of one's rejectors" that resulted from the patient's defensive attempts to keep something of himself from the clutches of the institution. Goffman concluded that some people outside mental institutions may derive a sense of being a person from joining a social unit, but that patients use secondary adjustments as a form of ritual insubordination whereby they obtained a sense of personhood by opposing in a thousand little ways the wishes of those in control of their social system.

Goffman's thesis is that the institutionalizing elements which were intended to produce model patients and a therapeutic milieu instead generated institutionalism, a counterproductive culture of passive resistance that rooted patients more firmly in the institution whose grasp they intended to escape.

THE REVISIT

Method

The years 1955 and 1956 marked a high tide of inpatients. The phenothiazine revolution, a growing negative attitude toward the value of hospitalization, milieu therapies, and the increased ability of patients to receive welfare were forces that have ensured a continuing ebb in the national inpatient census since then. In 1956, Saint Elizabeths' census peaked at more than 7,000; it has dropped to 2,700 today. From Goffman's point of view, how have these two decades of change affected his original asylum, Saint Elizabeths Hospital?

The two of us who are staff members were hardly in

a position to prowl the wards inconspicuously, sniffing out secondary adjustments and seeing the privilege system through the patient's eyes. To duplicate Goffman's vantage point, we undertook a study in which three students with little or no previous exposure to mental hospitals spent six weeks as observers on six inpatient wards. Their task was to observe and record the two phenomena described by Goffman: institutionalization and institutionalism. They were to look for evidence of the institutionalizing process by observing ward procedures and to assess institutionalism in patients by focusing on secondary adjustments.

Before going to the wards, the group developed a 24-item list of objectively verifiable characteristics from Goffman's book that was later consolidated into the following 10 categories:

1. Wanting to go to industrial therapy to get away from ward programs.
2. Doing favors for other patients.
3. No friends outside ward.
4. Bulging handbags, pockets, etc.
5. Repetitive "sad stories."
6. "Unauthorized" use of hospital objects.
7. Panhandling.
8. Employing or employed by another patient.
9. Doing favors for staff.
10. Territoriality.

These characteristics pertain to the specific secondary adjustments that Goffman felt were a result of patients' interactions with the asylum and were intended as a rough measure of institutionalism. Additional data included a description of each ward's daily activities. More subjective information was obtained during repeated visits to the same units over the six-week period as the observers developed relationships with patients. These data were then analyzed to produce the impressions in the Results section. The two authors on the staff then used the checklist to review each program and each patient's condition with the program staff. Institutionalization was measured by the number of structured hours per week, and institutionalism by the number of secondary adjustments in the patients in a given program.

In the 20 years since Goffman's visit, what was then the newest service in Saint Elizabeths Hospital has been converted from a traditional mental hospital inpatient service to a community mental health center. When the conversion occurred in 1969, the fence separating the building from the community was taken down. The building now houses four catchmented general psychiatric units, each consisting of a heterogeneous ward and outpatient team. There is a children's ward and separate inpatient treatment programs for alcoholics and drug addicts.

Results

On the three general psychiatric units, the patients fell into two categories: those whose average length of stay was about 15 days (the minority), and an older group, many of whom have been hospitalized on the ward for many years—a few as far back as Goffman's time.

TABLE 1
Ranking* of Programs in Terms of Institutionalization and Secondary Adjustments

Program	Institutionalization			Secondary Adjustments		
	N	Structured Hours/ Week	Rank	N	%	Rank
Addiction A	38	56	1	0	0	6
Alcoholism B	19	50	2	3	16	4
Alcoholism C	46	40	3	2	4	5
General Unit D	23	17–45**	4	11	48	3
General Unit E	20	16–43**	5	13	65	2
General Unit F	13	16–25**	6	11	84	1

*Ranking is from most to least on both measures.
**The vast majority of patients were at the lower end of these ranges.

In terms of institutionalization and institutionalism, we found sharp contrasts between the general psychiatric wards and those devoted to treating alcoholism and drug addiction. On the general wards there was some evidence of initiation rituals, the stripping process, and the privilege system, with minor differences from ward to ward. In fact, one ward granted no privileges at all to the new patients, reasoning that if a patient was well enough to leave the ward, he was well enough to become an outpatient. An underlife was found and there was ample evidence of secondary adjustments.

The programs for alcoholics and drug addicts contrasted sharply with the general units. Although patient stays were measured in months and ages were comparable to the short-term group on the general units, the stripping process and the privilege system were elaborated and formalized to a degree exceeding anything described by Goffman. For example, a recruit to the drug program who arrives for an admission appointment is seated in a chair facing one corner of a vacant room and asked to wait. If the patient protests that he was on time for the appointment, the wait is even longer, sometimes up to eight hours. When the patient enters the program, contact with the outside world ceases. House rules are elaborate and formalized. The privilege system contains multiple levels, and a large chart announces each patient's position and marks his progress. Another chart shows each patient's place, duties, and hours in the residential work system. Group activities are scheduled back-to-back from breakfast to bedtime, with the exception of an hour a day for "personal needs." The entire system is based on the philosophy that the patient must shed his former identity to be "reborn."

Our findings in the alcoholism programs were similar to those in the drug program, except that the institutionalization was less elaborate and formalized. However, despite this pervasive institutional milieu in both programs, we found much less evidence of secon-

TABLE 2
Diagnosis and Secondary Adjustment

dary adjustments and institutionalism than Goffman described.

A more surprising finding emerged when we compared these six wards with each other: there appeared to be an inverse relationship between institutionalization procedures and patient institutionalism (see table 1). The most institutionalizing programs had the least institutionalism, which brings a number of questions to mind. Are secondary adjustments a function of diagnosis and length of hospitalization? Apparently this is the case (see tables 2 and 3), but there is also evidence that these behaviors are present in recent admissions and in patients with a variety of diagnoses.

DISCUSSION

Our results seem to indicate an inverse relationship between institutionalization and institutionalism, but such a conclusion is unwarranted for several reasons.

We think that a patient's condition makes a difference in whether he will be subject to institutionalism. Goffman did not differentiate patients by diagnosis or other characteristics. Table 2 shows a high correspondence between schizophrenic or organic diagnoses and secondary adjustments.

A second possibility would be to accept the generic concept of institutionalism, adding the thesis that institutionalism is just one step in the larger process of placing a patient in another structured setting out of the hospital, such as a half-way house, foster home, nursing home, or the patient's own home. Thus we may have missed many patients who were institutionalized but were no longer in the hospital, seeing instead an atypical group of patients whose institutionalism was not complete and who were not discharged for this reason. This argument assumes that the "completely institutionalized" patient had moved on to other settings and would help to account for our finding that the patients hospitalized for more than one year do not show secondary adjustments to a greater degree than is shown in table 3. This generic premise, however, is modified further by the argument below.

A third argument is that institutionalism is produced by institutionalization, but that Goffman's secondary adjustments are not true indicators of institutionalism. This argument would include the suggestion that the social breakdown syndrome described by Gruenberg and associates (6) or recent similar studies are more valid signs of institutionalism than secondary adjustments. We believe our most institutionalizing programs do produce homogeneous attitudes, behavior, and speech. Goffman's concept of secondary adjustments fails to capture these basic changes.

A fourth argument is that Goffman's secondary adjustments are secondary to some severe mental illnesses rather than to an institutionalizing environment. Do the "revolving door" marginal patients show so-called secondary adjustment behavior? Did the preinstitutional "village madman" of past centuries show the same behavior? Answers to these questions might help clarify the validity of this argument.

A fifth argument, somewhat suggested by our findings, is that secondary adjustments result not from institutional structure but from institutional neglect.

We believe that all five of these arguments have merit and, taken together, explain our findings. In revisiting the asylum we considered diagnosis, length of stay, and degrees of a program's institutionalism. Goffman did not consider any of these fully. We do not doubt that institutionalism takes place, but we now suspect that Goffman did not accurately describe its characteristics because he failed to differentiate programs that had a great deal of institutionalization from those which did not.

This revisit has also forced us to face the question of whether institutionalization is as bad for all patients as was thought two decades ago. The most publicly admired of the six programs we surveyed are those with the most institutionalization. Still, extreme forms of regimentation are as distasteful today as they were in Goffman's time. We would suggest tentatively that extreme forms of institutionalization be adopted as part of a mental health program only as the last resort for certain otherwise untreatable patients because of the psychological pain it causes those patients and its economic cost to the public. Our observations suggest that if an institutionalizing program must be adopted to fill the needs of some subcategories of patients, it should be done under the following conditions: 1) vol-

untary admissions, 2) homogeneity of programs, 3) blending of staff-patient roles, 4) planned prolonged hospitalization, 5) nonpsychotic primary diagnoses, 6) heavy use of psychological and social restraints and little or no use of physical restraints or medications, and 7) prompt discharge at the patient's request.

Outpatient Treatment of Schizophrenia

BY NORRIS HANSELL, M.D., M.S.HYG., AND GRANT L. WILLIS, M.A.

The authors discuss the treatment of 575 schizophrenic patients over the past 15 years. They describe a shift the patients have experienced from reliance on inpatient treatment to heavy use of outpatient services. They have found that effective outpatient treatment for these patients involves a program of nearly continuous administration of neuroleptic medication combined with counseling and social and crisis services. A major component of the outpatient management of these schizophrenic patients is the education of the patients in how to regulate their own medication within a prescribed range. This educational component appears to add a measure of precision that enhances the safety and reliability of the treatment program.

WE ARE ENGAGED in the continuing study of 575 schizophrenic patients treated in a mental health center in an area of central Illinois that two decades ago had few local mental health services. In the past 20 years, local services have been developed to the point that the site of most care is near the patient's home. This shift to local services has occurred during the lifetime of some of our study patients and allows us to compare the appearance of their illness under both institutional and outpatient styles of treatment.

THE PATIENT GROUP

The median age of the 575 schizophrenic patients is 37 years; the youngest is 15 years old and the oldest is 88. Fifty-two percent of the patients are women. All but 18 have been hospitalized at least once, and most have been hospitalized two or more times. The diagnostic criteria have changed over the past decade but have remained conservative. The earlier criteria were presence of thought disorder and affect reduction, delusions, or hallucinations, all in the absence of gross brain or toxic disease. The more recent criteria also require a duration of episode of more than 6 months and the absence of intoxicated state or broad affect (1). Although the diagnoses were initially made by a number of different physicians, we established the diagnosis of all 575 patients in the study group. We regard this patient group as composed of seriously ill schizophrenic patients, either chronic remitting or chronic unremitting. We believe the group includes few mild, single-episode, or schizophreniform cases.

The study group represents a large percentage of the schizophrenic patients in our area who repeatedly undergo hospital or emergency care. For example, of all the schizophrenic patients admitted to local hospital care in 1975 from Champaign and Ford Counties, Ill. (population, 176,000), 82% are in our group of 575 patients. All but 7 of our study patients receive continuous or long-term/intermittent neuroleptic medication. Forty-one percent live alone, and an additional 11% live in group care, sheltered care, or nursing care facilities (most of these, but not all, are aged persons). Thirty-one percent of our 575 patients receive regular payments or pensions from welfare, Social Security, or veterans' agencies.

In 1975, 12% of our patients were hospitalized for at least 1 day, and 16% came to the hospital emergency room or the mental health center's crisis service. Two percent moved into distant hospital care after moving through local hospital care in 1975. Twenty-eight percent use day care and lodge-based social services to varying degrees.

We have made no attempt to discharge any of the 575 patients from continuing service, but we try to keep inpatient stays short. Counseling and social services are often suspended, sometimes for a prolonged period of time, after the resolution of life challenges. We attempt to find out whether neuroleptic medication is essential as well as to find the lowest effective dose of medication and the most convenient schedule of medication supervision that will work reliably. The average daily maintenance dose for our patients is equal to 2–5 mg of fluphenazine; the average daily dose during episodes is equal to 30–60 mg of fluphenazine.

The fact that using primarily outpatient services is a relatively recent phenomenon in central Illinois can be gathered by comparing two subgroups of our sample of 575 patients. An older cohort of 30 patients born in the 10 years following 1915 experienced an average of 72 days per person per year in state hospitals during the 3 years following 1962. The same cohort experienced an average of 5 days per person per year in state hospitals

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Hansell is Professor of Psychiatry, Northwestern University, Chicago, Ill.; Lecturer in Psychiatry, Harvard University, Boston, Mass.; and Attending Psychiatrist, Champaign County Mental Health Center, 1402 W. Park St., Urbana, Ill. 61801. Mr. Willis is Reception Service Officer, Champaign County Mental Health Center.

during the 3 years following 1971. The shift to new local services occurred in the interim. A younger cohort of 30 patients born in the 10 years following 1945 experienced a total of 77 admissions to a state facility in the 3 years following 1962 and a total of only 2 admissions in 1974 and 1975. The younger cohort continues to use local inpatient services occasionally (4 days per person per year). Thus it can be seen that in addition to a move to local inpatient services, there has been a major reduction in the length and total days of hospitalization in the past 15 years.

A major increase in the use of outpatient services has unfolded over the same interval. The older cohort made an average of 2 outpatient visits per person per year during the 3 years following 1962 and an average of 38 visits per year (including all contacts) in the 3 years following 1971. The contacts in 1963 were largely for counseling and sporadic chemotherapy. Ten years later the older cohort made contacts that involved an average of six types of service per year, including chemotherapy, counseling, day care, home visits, mutual-help groups, legal aid, court intervention, crisis services, and membership in the Lodge (a nonresidential, club-like setting for mutual-help groups and other services to assist in forming affiliations).

The younger cohort also made an average of more than 30 outpatient visits per year; these involved a similarly large variety of services. The younger cohort is not using as much inpatient care as the older group, but it is using more varied outpatient care more frequently. The comparisons within the older cohort and between the older and younger cohorts show that the interval between 1962 and 1975 has seen a distinct shift to outpatient care and to more varied types of care. However, there is a continuing use of inpatient care, and there is no sign that the total amount of care is decreasing.

RELIABILITY OF MEDICATION OVER DECADES

The accumulating evidence that some types of schizophrenia involve a biological disturbance with a lifelong pattern of risk, the clinical experience that neuroleptics decrease the likelihood of exacerbations in some schizophrenic patients (2–4), and the hazards of prolonged neuroleptic use (5) lead us to approach the proposal of chronic neuroleptic use carefully. If we determine that neuroleptics are essential for a given patient, we observe that patient to ascertain the lowest effective dose and propose arrangements for a long-term pattern of continuous or semicontinuous use of medication.

We deal with the problem of tardive dyskinesia by strictly assessing the necessity of neuroleptics, by using them intermittently if possible, by using the lowest effective dose, and by instructing the patient to call us if unusual mouth, trunk, or limb movements occur. More than four-fifths of our 575 patients omit their daily dose 1 or 2 days each week, except during episodes. Three of our patients have developed tardive dyskinesia in the past 2 years. All 3 have recovered after 1–12 weeks; 2 of these were hospitalized with psychosis when neuroleptics were withdrawn. These patients continue to present a problem; we have used reserpine during hospital episodes.

All of the individuals in our group of 575 schizophrenic patients have been counseled that their disease is likely lifelong, that it may involve altered brain biology, and that it is often substantially modifiable with chemical and social regulation. The counseling focuses on analogies to diabetes, on fluctuations in the course of the illness due to adaptational challenges, and on self-regulation of medication within a prescribed range. We tell our patients our opinion that lifelong care for their condition, if done with precision, does not result in an increase of sickness but in an increase of health and function. We also tell them that if their condition later warrants a less continuous mode of care we can shift our approach on the basis of strategic observations. We are concerned about the possibility that our informing the patients of our attitude of observation-based personal health planning might constrict a patient's overall situation, but we are not aware of any instance in which this has occurred.

Hogarty and associates (2) found that a high percentage of patients who were rehospitalized had experienced their exacerbations after they had stopped taking their medication. Similarly, in our group, not taking medication was highly correlated with a return of symptoms and with rehospitalization. It often takes 3–6 months or longer for such exacerbations to occur. Drug holidays lasting several days to several weeks usually do not accurately foreshadow longer-term consequences. Patients need to understand these time relationships because, after they learn that they likely have a lifelong program ahead of them, many show a keen interest in personally assessing the effects of their medication.

Our goal for these schizophrenic patients is the reliable administration of the lowest effective amount of medication over an interval of decades. Therefore, we focus the clinical relationship on teaching patients enough about their disease, the drugs needed to control it, and their reactions to the drugs so that their full energies can be applied to the purpose. If a patient wants to stop taking medication when he or she is doing well clinically or if a patient voices an intention to assess the consequences of stopping medication, we encourage him or her to do so but only under close supervision.

Patients are instructed in a method for looking for the earliest signs of deregulation, i.e., the symptom cluster of disturbance of the sleeping-waking cycle, floating affects (sadness, panic, suspicion, perplexity), difficulty concentrating, preoccupation with a narrow range of thoughts, and loss of pleasure in social contacts. In the past 2 years, 38 or our 575 patients have assessed the effects of stopping medication; 36 of these

patients experienced a return of the early-warning symptom cluster or frank psychosis and returned to the use of medication.

Two other reasons for stopping taking medication are side effects, broadly considered, and cost. Early in treatment, we ask our patients to work closely with us if side effects occur. We have concluded that patients who experience side effects and do not tell us about them or work with us on their control eventually stop taking the offending drug. Early in treatment we encourage our patients to discuss side effects fully, including the subtler forms of akathisia (6). More than two-thirds of our 575 patients experienced some side effects, most of which were manageable with persistent attention. Twenty-two percent are taking an atropinic material for control of motor side effects. Forty-six percent have done so occasionally. If cost becomes a controlling factor in whether or not a patient continues to take medication, the center assumes or defrays the cost.

Of equal importance in establishing a reliable pattern of medication administration over decade-length intervals of time is helping the patients achieve a substantial degree of self-regulation of medication within a prescribed range. Most of our patients do best when taking the lowest dose that will control the sleep disturbances and floating affects. At the same time, the patients are also instructed in a method for increasing their medication during episodes of life challenge. Teaching patients to regulate themselves within a range offers major gains in reduction of side effects, reduction of overall amount of medication taken and thus of the chance of developing tardive dyskinesia, and enhancement of reliability.

We counsel patients to use some of the following experiences to signal that they are taking too low a dose: a breakup in the orderliness of the sleeping-waking cycle, diminished concentration or preoccupation with a few ideas, floating affects, ideas of influence or reference, and such psychosomatic symptoms as headache or paresthesia. In raising the dose, we instruct patients to increase it by a half and wait 3 days to assess the effect. They may repeat this maneuver several times.

Similarly, we counsel patients that if they experience forms of dissociative phenomena or sleeping-on-inactivity they might be taking too high a dose. In this event we instruct patients to reduce their dose by a third and wait 3 days to assess the effect. We estimate that more than 400 of the 575 patients in our study group are systematically increasing and decreasing their own doses successfully. The rest of the patients, most of whom are more than 50 years old, prefer to be given an unvarying dose routine and to make deviations from it only on direct instruction from a physician.

Of the total group, 28 receive all or part of their medication in the form of depot fluphenazine. Seven of these are given their injections by a visiting nurse; the rest are given the drug in the emergency room of a local general hospital. Most of these patients were not successfully managed in a program of self-regulation and also experienced repeated hospitalizations when they stopped taking medication. Patients in this group must give their consent and continuing cooperation for any depot fluphenazine administration, so education and counseling are still important for them. We regularly lower the dose and stretch the interval between injections to reestablish the minimum effective amount.

There are two main principles in gaining the cooperation of patients for decade-long programs of medication. First, we recommend the use of no more or less medication than is necessary and take steps to gain information on this point. Second, the actual consequences of any decision to stop or change medication deserve a close watch; we will assist the patient at any time to make such a decision.

THE SELF-REGULATION GROUP

Many of our patients who eventually became quite successful in self-regulation of their medication seemed to have learned such skills most effectively in a group context. The self-regulation group, which was organized for this purpose, meets weekly under the direction of a psychiatric nurse. The group members discuss and react to each other's problems with medication for control of psychiatric symptoms. The composition of the group is constantly changing. Some patients use it 4–16 times, mainly during the induction phase; a few attend almost indefinitely. The size of the group ranges from 8–22 members. Of our 575 patients, about 55 are attending or have attended the group.

The usefulness of the group resides in the fact that it provides a setting for an individual to learn what he or she may need to know to make decisions about medication use and for the more skilled to teach the less skilled in self-regulation. Learning occurs through the reports each patient gives on the state of control of his or her target symptoms, together with reports on side effects and defining objectives for improving the state of self-regulation. Members take individual responsibility to contact their physician to discuss any changes or actions they wish to take regarding medication. The most useful features of the group are its ability to convert reluctant or careless medication users into skilled self-regulators and its role in raising the average level of self-regulation to close to the best level represented in the group.

ADAPTATIONAL EPISODES

For well-controlled schizophrenic patients the onset of an adaptational episode is typically not first signaled by the presentation of psychotic behavior or hallucinations. Difficulty sleeping, difficulty concentrating, lowered work endurance and task focus, floating affects

(including sadness, panic, perplexity, anger, suspicion, and certitude), and, for a smaller group, frank ideas of reference or preoccupation with a few ideas usually signal the onset of an episode. Coincident with these early signals of decompensation are the loss of enjoyment in being with people and a loss of a feeling of attachment to friends and kin.

We try to teach schizophrenic patients to be more effective managers of their adaptational episodes. During such crises most of our patients increase the dose of medication that is usually effective in controlling their symptoms; this increase averages a doubling or tripling of their ordinary dose and lasts from several weeks to several months.

At the beginning of an adaptational episode we encourage patients to increase their dose of medication and to watch their sleeping-waking and resting-working rhythms as markers of the completeness of their regulation. We then encourage them to feel for a comfortable pace in entering and moving through the situation. We encourage them to get rest, food, water, and relaxation during the period of challenge, remembering that the problem-solving effort may extend over many weeks. We ask them not only to try to formulate the current problem but also to become aware of what they want for the future; we also ask them to describe the past in such a way as to define the current situation in the context of a distinct past and an envisionable future. We encourage patients to name their helpers and to keep in regular reporting contact with them. The regulation of adaptive work seems to proceed best when all parties in the process have an opportunity to form a task group. Above all, we ask our patients to avoid getting exhausted and to avoid isolation. We encourage them to stay hooked to others, to a path, and to a pace.

OTHER CHEMICALS

The outpatient care of schizophrenic patients presents a continuing need to be aware of the interaction between the disease and the medications used for its control and alcohol, sedatives, minor tranquilizers, anorectics, and decongestants. The clinical problems arising from these interactions are not uncommon. Sixty-three of our 575 patients had one or more problems involving such interactions in 1975.

The problem we find with alcohol is that patients sometimes attempt to use it to control schizophrenic symptoms, particularly the sleep disturbances and floating affects. Not only is alcohol ineffective in the control of these symptoms in schizophrenia, but time is lost and attention is diverted from more precise methods for regulation of symptoms. The clinical problem arising from the use of minor tranquilizers, sedatives, and soporifics is the same as the problem with alcohol. These materials are much less efficient than neuroleptics in regulating the sleeping-waking cycle and the floating affects of schizophrenia. In addition, it has been our experience that the duration of action of minor tranquilizers can be measured in hours, in contrast to the much slower, enduring effects of neuroleptics. The too-brief duration of action of minor tranquilizers yields inherently destabilizing aftereffects for both patient and clinician.

Of a different nature are problems with amphetamines, ephedrine, and congeners. Amphetamine psychosis has long been known to mimic schizophrenia; it is not so widely recognized that continuing use of small amounts of sympathomimetics has a deregulating effect on chronic schizophrenia. Their use often yields subtle or dramatic exacerbations in the course of the illness, the origin of which is not apparent without precise inquiry. In our group of 575 patients, 26 have shown such interactions; this number is likely an underestimate because we might not have recognized many of the events due to the fact that we came to appreciate this matter only recently.

It is not mainly sympathomimetics prescribed by physicians that constitute the bulk of this problem but the presence of these materials in over-the-counter pharmaceuticals, particularly diet pills and items intended as cold pills and respiratory decongestants. For example, we have found three diet pill items marketed locally that contain phenylpropanolamine, namely Diet-Trim, Hungrex, and Slender-X. The list of proprietary decongestants containing phenylephrine, phenylpropanolamine, ephedrine, and congeners is long. For example, it includes Allerest, Benzedrex, Contac, Coricidin "D," Dristan, Mistol, Neo-Synephrine, Novahistine, Ornex, Romilar, Sinarest, Super-Anahist, Vicks-Sinex, and 4-Way Cold Tablets. We ask our patients to avoid the use of decongestants altogether; there seems to be a difference in the number of exacerbations due to this problem during the winter season of respiratory infections.

SUMMARY

In central Illinois the period since the early 1960s has seen a shift in the management of chronic schizophrenia from heavy use of inpatient treatment to heavy use of outpatient treatment. For schizophrenic patients who might otherwise be repeating users of hospital service, effective outpatient service appears to involve a program of continuous, or nearly continuous, neuroleptic medication combined with counseling, social, and crisis services. A substantial amount of education focused on the patient's role in self-regulation of medications within a prescribed range appears to allow useful improvements in safety, precision, and reliability.

Change in ABPN Part II Examination Format

Beginning with the October 1977 American Board of Psychiatry and Neurology Part II examination, the one hour of oral examination in Neurology previously administered to Psychiatry candidates will be replaced by a written examination. The written examination is based on a series of audio-visual vignettes of neurological patients. Each vignette will last approximately three to four minutes and will be followed by written, multiple-choice questions pertinent to the brief patient presentation. There will be no examiner involvement or patient contact in this section.

Thus, all new Psychiatry candidates will take three sections during the Part II examination:
1 one-hour examination in Clinical Psychiatry (live patient)
1 one-hour examination in Clinical Psychiatry (audio-visual)
1 one-hour examination in Clinical Neurology (audio-visual)

The Medical Basis of Psychiatry

BY ARNOLD M. LUDWIG, M.D., AND EKKEHARD OTHMER, M.D.

The authors state that the medical model represents the most useful and appropriate model available for the practice of psychiatry. They discuss the implications for psychiatry of the three essential features of the medical model: the concept of disease and diagnosis, the concept of etiology and treatment, and the nature of the doctor-patient relationship. They conclude that the adoption of the medical model for psychiatry would have profound implications for residency training, continuing education, delivery of care, standards of ethical and professional practice, dealings with third-party payers, and conflicts with other professions.

THE OBJECTIVE of this paper is to clarify the essential features of the medical model for the practice of psychiatry. The entire thesis derives from the basic premise that the primary identity of the psychiatrist is as a physician (1, 2).

Because of the "model muddlement" that has beset psychiatry (3), comment is necessary about models in general. Models are neither real nor sacrosanct; they are abstractions invented by the human mind to place facts, events, and theories within an orderly framework (3). Just as a grid or wheelspokes design may determine the layout of a city, models provide conceptual templates for the organization of information. Because models are neither true nor false, they can be judged only by their relative usefulness or uselessness. A model that is not sufficiently comprehensive, that excludes contradictory or incongruous data, or that requires frequent restructuring to accommodate new information ceases to be either intellectually gratifying or of practical value. It is our contention that the medical model represents the most useful and appropriate model available for the practice of psychiatry.

THE MEDICAL MODEL

There are three essential features of the medical model: the concept of disease and diagnosis, the concept of etiology and treatment, and the nature of the doctor-patient relationship. We will discuss the implications of each of these features for psychiatry.

The Concept of Disease and Diagnosis

The primary signs and symptoms of disease are often characterized by five major features: 1) with the exception of genetic-congenital conditions, they indicate a change from a previous healthy state; 2) they represent deviations from an appropriate reference group for the individual; 3) they display varying probabilities of association (e.g., certain signs occur almost always with certain symptoms and vice versa); 4) their cross-sectional patterns of association may differ from their patterns over time; and 5) they contribute to or are associated with impairment in psychological and social functioning (i.e., secondary signs and symptoms).

When different patterns of signs and symptoms tend to be associated with different patterns of morbidity and/or mortality, different diagnostic labels drawn from an accepted classificatory scheme are employed to differentiate among these patterns, each of which is presumed to be produced by natural causes. The diagnosis of disease, then, represents an attempt at categorization of information and a probability statement regarding the expected association among certain signs and symptoms with their course over time, their underlying pathological basis, and their possible etiological sources. Because of modern detection and screening methods, the early stages of some diseases may be established by "silent" signs before the appearance of any symptoms.

There are four main types of disease diagnoses used in medicine. The degree of reliability and precision in diagnosis is directly related to the degree of knowledge of primary cause of the particular pattern of symptoms and signs. If the specific etiology of this pattern can be determined, either in vivo or post mortem, a causative diagnosis can be made (e.g., bacterial infection). If only tissue or organ changes can be demonstrated (without knowledge of their cause), a pathological diagnosis can be made (e.g., cancer). If only the syndromatic association of symptoms and signs and their natural history are known, a descriptive-prognostic diagnosis can be made (e.g., Ménière's disease). If isolated symptoms are not associated with any signs, then only a symptomatic diagnosis can be made (e.g., tension headache).

Critics who invoke the imprecision and poor reliability of many psychiatric diagnoses as an argument

Dr. Ludwig is Professor and Chairman, Department of Psychiatry, University of Kentucky College of Medicine, Lexington, Ky. 40506. Dr. Othmer is Professor, Department of Psychiatry, University of Kansas College of Medicine, Kansas City, Kans.

TABLE 1
Categorization of Selected Affective-Cognitive-Behavioral Disorders

Disorders with Biological Dysfunction			Disorders with Social-Psychological Dysfunction		
Neuropsychiatry	Functional Psychiatry	Medicopsychiatry	Social Work	Social Psychology	Clinical Psychology
Epilepsy	Schizophrenia	Hypothyroidism	Problems of living	Criminology; forensic issues	Problems of living
Headache	Bipolar affective illness	Hyperthyroidism	Minority problems	Social deviance	Learning disabilities
Dementia; organic brain syndrome	Unipolar affective illness	Alcoholism	Poverty	Anomie syndrome	Marital difficulties
CNS syphilis	Episodic dyscontrol syndrome	Obesity	Family troubles	Dependency syndrome	Existential depressions
Huntington's chorea	Sociopathy	Hypochondriasis	Coordination of community services		Adjustment reactions
Narcolepsy	Anxiety; phobic reactions	Drug dependence			Personality disorders
Delirium	Conversion hysteria	Sexual dysfunction			Coping deficits
Parkinsonism	Hyperkinetic syndrome	Psychosomatic problems			
Mental retardation	Borderline syndrome	Anorexia nervosa			

against their nonmedical nature fail to realize that a similar situation pertains to many nonpsychiatric medical diagnoses (4). This relative unreliability in diagnosis does not indicate that diagnosis should be abandoned but that more precise criteria should be developed.

On the basis of the above considerations, psychiatric disease would pertain to any affective-cognitive-behavioral disturbances that impair a person's adaptive and adjustment responses and in which some known, suggestive, or presumed biological abnormalities or dysfunctions (mainly genetic, biochemical, or physiological in nature) play a significant role. In certain instances, this biological dysfunction represents the necessary but not the sufficient condition for the appearance of the disease (e.g., schizophrenia); in other instances, both the necessary and the sufficient condition (e.g., toxic psychosis); and in still other instances, the sufficient condition alone (e.g., anxiety attack). In all instances, this biological dysfunction will be associated with altered forms of brain activity, reflected in some impairment in reception of information or sensory stimuli, cognitive or central processing of signals, and general behavior outputs. Concern for the biological components of disease does not preclude an understanding of environmental factors.

This concept of disease and nondisease has profound implications for psychiatry. Psychiatry previously has relinquished responsibility for the care and management of diseases with known physical etiologies (5), such as general paresis, mental retardation, pellagra, and epilepsy. To a certain extent, this trend is continuing in the areas of alcoholism and drug dependence. Psychiatry now assumes primary responsibility for diseases of unknown etiology, such as schizophrenia and manic-depressive psychosis, and for a multitude of social-psychological problems presumably caused by metapsychological conflicts, faulty learning, poor interpersonal communications, and social inequities. On the basis of a medical definition of psychiatric disease, the proper purview of psychiatry should be modified to include certain borderline conditions that overlap with neurology and medicine and to exclude those clearly in the domain of the social sciences.

Psychiatric diseases may be classified as either neuropsychiatric, medicopsychiatric, or functional psychiatric. The designation "functional" indicates that, either because of inadequate theories or limited technology, the presumed biological dysfunction has not yet been established. Excluded from the disease concept are so-called problems of living, social adjustment reactions, maladaptive learning patterns, situational depressions, and various social deviance syndromes because it is assumed that sustained biological dysfunctions are neither necessary nor sufficient for their appearance and that somatic therapies are not indicated for their treatment. Personality disorders, existential depression, and certain learning disabilities would be more appropriately placed in a gray zone in terms of presumed biological dysfunction. Only the accumulation of more scientific knowledge can determine whether these disorders constitute psychiatric disease or not.

Table 1 presents a categorization of some selected disorders to illustrate the presumed areas of special expertise of the psychiatric physician with respect to

TABLE 2
Selected Types of Disease Theories

Type of Theory	Etiological Requirements	Example of Treatment	Level of Treatment
Infectious (e.g., bacterial and viral infections)	Koch's postulates; presence of specific antibodies	Germicidal agents	Curative
		Increase in immune response	Compensatory
		Suppressant agents	Syndromatic
		Symptomatic agents	Symptomatic
Deficiency state (e.g., rickets, scurvy, dehydration)	Decrease in necessary nutrients, minerals, or hormones; reversal of pathology with replacement	Replenishment	Curative
Excess state (e.g., Cushing's syndrome, acromegaly, atherosclerosis, hypercalcemia)	Increase in necessary nutrients, minerals, or hormones; reversal of pathology with depletion	Dietary control	Curative
		Counteracting agents, radiation, surgery	Compensatory
Imbalance (e.g., acid-base or electrolyte imbalance, cardiac arrhythmia)	Hyperplasia or hyperfunction versus hypoplasia or hypofunction of organ, tissue, or system	Agonist or antagonist	Compensatory
		Corrective surgery	Curative, compensatory
Toxicity (e.g., heavy metal poisoning, silicosis, radiation sickness)	Presence of toxin, poison, noxious agent, or abnormal metabolite	Decrease in toxin by binding agents, antidotes, antisera	Curative, compensatory
		Symptomatic agents	Symptomatic
Immune-autoimmune (e.g., asthma, hives, collagen disease, rheumatoid arthritis)	Antigen-antibody response with local or general reaction	Desensitization	Curative, compensatory
		Antiallergic agents	Syndromatic, symptomatic
Continuum (e.g., essential hypertension)	Deviation from "normal" range	Corrective agents	Compensatory, syndromatic, symptomatic
Traumatic stress (e.g., traumatic arthritis, fracture, noise deafness)	Anatomic and/or functional pathology secondary to trauma	Surgical repair	Compensatory
		Symptomatic agents	Symptomatic
Degenerative-destructive (e.g., cataract, aseptic necrosis, tumor)	Anatomic and/or functional pathology without external trauma	Prosthesis	Syndromatic
		Surgical repair	Compensatory, syndromatic
Genetic (e.g., Huntington's chorea, phenylketonuria, idiopathic epilepsy, sickle-cell anemia)	Positive family history; identification of abnormal functions or structures	Supplemental agents	Compensatory
		Prosthesis	Syndromatic
		Surgery	Compensatory, syndromatic
		Symptomatic agents	Symptomatic
Congenital (e.g., cleft palate, mongolism)	Negative family history; identification of abnormal functions or structures resulting from intrauterine or birth factors	Prosthesis	Syndromatic
		Surgery	Compensatory, syndromatic
		Symptomatic agents	Symptomatic
Secondary disease (e.g., Addisonian crisis, radiation burn, dumping syndrome)	Side effects or complications of treatment for primary disease	Substitutive agents	Curative, compensatory
		Symptomatic agents	Symptomatic

differential diagnosis and primary responsibility for treatment. Since not all patients presenting at mental hygiene clinics, emergency rooms, or physicians' offices have a psychiatric disease, the psychiatrist should be proficient in distinguishing among those disorders potentially associated with a biological dysfunction and those with a social-psychological dysfunction. Once this determination is made, the psychiatrist should assume primary therapeutic responsibility for the former disorders; nonmedical professionals might assume primary responsibility for the latter. This does not mean that the psychiatrist should focus exclusively on disease and the nonmedical professional on problems of living. The issue is one of emphasis and expertise. If the physician chooses to work with some "clients," which must always remain his or her prerogative, then he or she cannot claim any special expertise over his or her nonmedical colleagues, especially since their training in this area may be superior.

The Concept of Etiology and Treatment

In general, levels of treatment tend to correspond directly to the degree of knowledge available about etiology of disease. We may designate these levels of treatment as curative, compensatory, syndromatic, and symptomatic. Curative treatments pertain to elimination of causative agents or factors with consequent reversibility of damage and reduction of the need for further treatment. Compensatory treatments pertain to the minimizing of further dysfunction and the maximizing of existing function. Syndromatic treatments pertain to the suppression of major manifestations of

TABLE 3
Etiological and Treatment Aspects of Psychiatric Diseases

Item	Type of Etiological Theory	Example of Treatment	Level of Treatment
Functional psychiatry			
Schizophrenia	Deficiency state, excess state, imbalance, toxicity, immune-autoimmune, and genetic	Megavitamins	Compensatory
		Major tranquilizers	Compensatory, syndromatic
		Anticholinergic agents (for drug side effects)	Symptomatic
Bipolar affective illness	Deficiency state, excess state, imbalance, and genetic	Lithium	Curative*, compensatory, syndromatic
		Major tranquilizers	Compensatory, syndromatic
		ECT	Syndromatic*, symptomatic
Unipolar affective illness	Deficiency state, excess state, and genetic	Tricyclics and monoamine oxidase inhibitors	Compensatory*, syndromatic
		ECT	Syndromatic
Sociopathy	Deficiency state, imbalance, immune-autoimmune, genetic, and congenital	Antidepressants	Compensatory*
		Symptomatic drugs	Symptomatic
Anxiety; phobic reactions	Excess state and imbalance	Minor tranquilizers and sedatives	Symptomatic
		Systematic desensitization	Curative, compensatory, syndromatic
Conversion hysteria	Excess state (e.g., corticofugal inhibition)	Narcosynthesis	Compensatory, syndromatic
		Hypnosis	Compensatory*, syndromatic
Medicopsychiatry			
Alcoholism	Deficiency state, excess state, toxicity, continuum, genetic, and secondary disease	Disulfiram	Curative*, syndromatic
		Sedatives and minor tranquilizers	Symptomatic
		Vitamins	Compensatory
		Aversive conditioning techniques	Syndromatic, symptomatic
Drug dependence	Deficiency state, excess state, immune-autoimmune, toxicity, and secondary disease	Methadone	Compensatory, syndromatic, symptomatic
		Antagonist agents for overdose or prevention	Compensatory, syndromatic
Obesity (bulimia)	Excess state, imbalance, continuum, genetic, and secondary disease	Diet control	Curative
		Amphetamines	Compensatory, syndromatic
		Behavioral techniques	Curative, syndromatic
		Surgical bypass	Syndromatic, symptomatic
Primary hypochondriasis	Imbalance and secondary disease	Suggestion (placebo)	Symptomatic
		Symptomatic agents	Symptomatic
Hypothyroidism	Deficiency state and secondary disease	Replacement	Compensatory
Neuropsychiatry			
Idiopathic epilepsy (temporal lobe type)	Excess state, genetic, and congenital	Anticonvulsants	Syndromatic
		Surgery	Compensatory
Huntington's chorea	Imbalance, degenerative-destructive, and genetic	Haloperidol	Symptomatic
		Symptomatic agents	Symptomatic
Presenile dementia (Alzheimer's and Pick's disease)	Toxicity, degenerative-destructive, and genetic	Symptomatic agents	Symptomatic
Parkinsonism	Infectious, deficiency state, and degenerative-destructive	L-dopa	Compensatory
		Anticholinergic agents	Syndromatic
		Amantadine	Syndromatic
Narcolepsy	Imbalance, genetic, and congenital	Stimulant agents	Syndromatic
		Antidepressants	Syndromatic
Mental retardation	Infectious, deficiency state, excess state, toxicity, immune-autoimmune, continuum, degenerative-destructive, genetic, and congenital	Diet (phenylalanine)	Compensatory
		Symptomatic agents	Symptomatic
		Special learning techniques	Compensatory

*We are not sure of these levels of treatment.

the illness but do not ensure correction of the underlying dysfunction or elimination of all residual effects. Symptomatic treatments pertain to the suppression of selective manifestations of the illness without elimination of underlying causes or residual effects.

It should also be noted that the reliance on scientific

method to assess efficacy of treatment becomes increasingly important as less is known about the actual etiology of a particular disease. Single case studies may be sufficient to evaluate the effectiveness of treatment intervention for such causative diagnoses as inguinal hernia or pellagra, but double-blind controlled treatment studies are essential to evaluate the relative efficacy of treatment for such syndromatic diagnoses as migraine headache or bipolar depressive illness.

As we have indicated, there are many etiological theories of disease. Table 2 provides a list of 12 major types of medical disease theories, examples of specific diseases, the requirements to test the theories' validity, examples of treatments used, and current levels of treatment approaches. This categorization is arbitrary in that there are several etiological theories under investigation for any particular disease. In general, the more theories that are advocated for a particular disease and the more a unitary theory is proposed for all diseases, the less is known about actual etiology.

Table 3 shows that similar theories are operative in the biological investigation of most psychiatric diseases,[1] although inadequate conceptualization and technology prevent the gathering of objective laboratory and other diagnostic tests. Just as there are numerous etiological disease theories under investigation in cancer research (e.g., infectious, toxic, imbalance, degenerative, and autoimmune), a similar situation pertains to such psychiatric diseases as schizophrenia. Despite unconfirmed etiologies, these theories of disease provide many avenues for experimental investigation and the development of specific, more effective therapies.

There has been sufficient research on stress and altered levels of sensory stimulation in psychiatry to indicate the profound effect of many environmental variables or situations on the biological functioning of individuals. Acknowledged environmental influences are not incompatible with a disease concept of etiology, but their often vague conceptualizations are. However, even if environmental variables can be specified, it is essential to presuppose or demonstrate the existence of a biological diathesis preceding or a biological dysfunction following the introduction of environmental variables as a necessary or sufficient condition for the appearance of disease. When no sustained biological dysfunction can be demonstrated or presumed, no disease can be said to exist.

The Doctor-Patient Relationship

The physician is granted awesome responsibility, aptly termed "Aesculapian authority," for the care and welfare of the patient (6, 7). The physician makes life and death decisions about patients; violates their bodily integrity and privacy through physical examination, diagnostic procedures, and surgery; and gains access to their innermost thoughts. This responsibility is held in check by equally awesome ethical obligations to act in the best interests of patients, to maintain confidentiality, and to provide quality care.

In his or her assessment of patients, the physician may judge the patients to be sick, thus granting a socially sanctioned decrease in general responsibility and implying that the illness cannot be due to or cured by volition alone (3, 7). However, the sickness does not need to correspond to the particular sick role adopted by certain patients (8). This general viewpoint stands in contrast to most nonmedical models, in which a patient may be regarded as not sick (i.e., as a client or an analysand) and therefore not granted the sanctioned decrease in responsibility. The patient's problem may be viewed as bad or deviant and caused by his or her witting or unwitting decisions or learning.

Since the special responsibilities and prerogatives of physicians have at all times pertained only to the treatment and prevention of sickness or disease, it could legitimately be questioned whether psychiatrists abrogate their authority as physicians when they treat only "nonsick" individuals by means of individual counseling, family and group therapy, or sensitivity sessions.

THE PRACTICE OF PSYCHIATRY

The relevance of the medical model for psychiatry must start with the premise that the psychiatrist is a physician. As a prerequisite for actual diagnosis and treatment, the psychiatric physician must obtain an adequate and comprehensive data base. This includes detailed and skillful interviewing of the patient or other informants and careful physical, neurological, and mental status examinations.

Having elicited special symptoms and signs, the psychiatric physician then resorts to the process of differential diagnosis in an attempt to account for the various symptoms and signs according to the probability of their association with certain diseases or nondisease reactions. After the formulation of a differential diagnosis, a specific diagnosis is needed. For this process, the psychiatric physician uses a variety of laboratory tests and specific diagnostic procedures to rule out certain diagnoses and to confirm others. For the functional psychiatric diseases, for which there may not be specific laboratory tests, syndromatic diagnoses may be made on the basis of standardized diagnostic criteria (9).

No diagnosis of disease should be made that does not carry with it implicit information about likely age of onset, course and duration, prognosis, and type of treatment available. The diagnosis of psychiatric disease should not be made by exclusion but on the basis of positive biological or behavioral criteria.

As to the administration of therapy, the psychiatrist should possess particular competence in and knowledge of the use, side effects, and complications of all appropriate somatic therapies; certain short-term procedures, such as hypnosis, behavior modification, and

[1]Because of space limitations, general references are not provided; they will be furnished by Dr. Ludwig on request.

UNIVERSITY COLLEGE OF MEDICINE LIBRARY

biofeedback techniques to treat conditions for which somatic therapies are not as yet very effective (e.g., anxiety and phobic neuroses and hysterical conversion reactions); and skill in the selective administration of supportive, insight-oriented, and problem-solving techniques to resolve problems confounding, contributing to, or complicating the primary disease.

Group therapy and ward management programs are entirely compatible with the medical model, provided they meet the three following criteria: 1) they should not overlook the biological component of disease; 2) they should be designed to increase treatment compliance; and 3) they should promote optimal functioning of patients. In his or her role as physician, the psychiatrist must view the patient as something more than his or her primary disease; the patient may display many maladaptive attitudes and behaviors existing independent of the disease that influence recovery and rehabilitation. In order to facilitate recovery and optimal functioning in patients, the psychiatrist may use psychosocial interventions as the only means available to modify harmful attitudes and behaviors.

With medicopsychiatric and neuropsychiatric diseases, the psychiatric physician should be sufficiently competent to undertake the primary treatment of most of these patients, in consultation, if necessary, with appropriate specialists. It represents fragmented patient care, for example, to refer a depressed person to a neurologist for treatment of headaches and to an internist for management of obesity and mild hypertension.

BEYOND DISEASE

It is essential to emphasize that management of the sick patient entails far more than the diagnosis and treatment of disease; the patient's illness must be addressed as well. According to Barondess (10), a disease represents a biological event of a pathogenic nature that can be understood mainly in scientific terms (i.e., objective, quantitative, and reproducible). An illness, on the other hand, is a human event and represents "a grouping of discomforts, dysfunctions and resultant personal and social dislocations occurring in a person, and representing the interaction of that person with a disease" (p. 154). Illness must be understood as an important life event, associated with many others and embedded within a matrix of concerns, hopes, fears, and responsibilities experienced by the patient. A physician whose role transcends that of scientist is obligated to address not only the diseased condition but also the person who is ill and his or her immediate family, who may be distressed and confused by the situation.

As long as the medical model pertains to the care of patients, its dependence on science will never be complete; there will always be room for the art of medicine. In the practice of this art, the psychiatric physician has the opportunity to bring all of his or her interviewing skills, perceptivity, and empathy to bear, much in the manner of any adept physician (1).

Those who discount the medical model because of its presumed emphasis on organ pathology and disease process rather than on the whole individual not only possess a limited concept of disease but also ignore the entire idealistic tradition of medicine. Humanism and a belief in the basic dignity of man are not the monopoly of psychiatry. They are implicit in the oath of Hippocrates, accepted by all physicians. These values can be just as easily imparted during a brief physical examination with the administration of diagnostic procedures as during an insight-oriented psychotherapy session. The extent to which these values are not imparted to patients is not so much a failing of the medical model as a failing in the practicing physician. There is no inherent contradiction between the treatment of disease and care and concern for the ill individual.

Some have impugned the medical model as too reductionistic or restrictive to deal with the complexities of human nature. Such criticisms are more pejorative than legitimate. If there is reductionism in the medical model, it pertains only to an emphasis on specificity and the elucidation of causality. If there are restrictions in the medical model, they pertain to its emphasis on objectivity and scholarship, its application of contributions from science, and its commitment to distinguishing fact from fiction in all aspects of psychiatry.

The adoption of the medical model for psychiatry would have profound implications for residency training, continuing education of practitioners, revisions of standards for Board certification, the delivery of psychiatric care, education of the public about the proper role of the psychiatrist, the establishment of standards of ethical and professional practice that discourage radical schools of thought, negotiations with third-party insurance payers, and territorial conflicts with other professions. This indeed will represent a formidable challenge for psychiatry. Such changes can represent only a beginning that reaffirms the foundation of psychiatry in medicine.

A Comparison of Videotaped and Live Patient Interview Examinations and Written Examinations in Psychiatry

BY DONALD H. NAFTULIN, M.D., GEORGE H. WOLKON, PH.D., FRANK A. DONNELLY, M.A., RODNEY W. BURGOYNE, M.D., FRANK M. KLINE, M.D., AND HOWARD E. HANSEN, M.D.

The authors scored the examination performance of 28 psychiatrists who were tested after conducting an interview with a real patient and after seeing a videotaped interview with an actor playing the role of either a psychotic or a neurotic patient. They also scored the performance of 15 of the same examinees who completed a written examination. Eighty-five percent of the examinees reported that the videotaped interview examination was a useful learning experience, and 81% said that it was a useful testing experience. The examiners' feelings varied regarding the use of the standardized videotaped format for certification and recertification of psychiatrists.

THE AMERICAN BOARD of Psychiatry and Neurology (ABPN) initiated the use of a videotape of an actual patient interview during Part II of the Board examination in March 1975 (1). A systematic report of the effects of this new method of assessment is not yet available. Voluntary anecdotal reactions of candidates and examiners have been mixed. If the Board increases its current responsibilities by broadening its scope from certification to recertification as well, a videotaped interview of a real patient or an actor or actress is a potential means of developing a more standardized, generalizable, and economical assessment method of a psychiatrist's competence.

The College of Family Physicians of Canada (2) and the American Board of Pediatrics (3) have introduced simulation methods in their certification examinations with reported success. Although some studies support correlations between a clinician's performance with patients and his or her ability to be examined by means of a real or videotaped physician-patient interaction (4–6), a literature search we conducted revealed no such reports involving psychiatrists specifically. We also found no comparisons of performance in any field between situations in which the clinician knew the interview was a simulation and those in which he or she did not know it was a simulation. Furthermore, unpublished studies by the ABPN suggest that correlations exist between high written performance scores and high oral examination scores, but supportive data for such statements are not available and have been questioned in published studies (7–11). In an effort to address some of these concerns, we undertook a study with the following questions in mind:

1. What are the similarities and differences and advantages and disadvantages of assessing a psychiatrist's skills by means of his or her conducting an observed clinical interview and then being questioned by examiners as compared with his or her observing a videotaped clinical interview and responding to a set of standardized questions asked by examiners?
2. Do the two methods of assessment differ as to examinee performance ratings and as a learning technique in the opinions of both examinees and examiners?
3. What is the relationship between each of these assessment methods and a written objective examination?
4. Does it make a difference in performance scores on the videotaped interview examination if the patient is neurotic or psychotic or if the examinee is or is not informed that the patient being interviewed is an actress or actor?

METHOD

Examinees

A group of 28 psychiatrists who recently completed an intensive review of psychiatry and neurology course in preparation for Part I or II of the ABPN examination volunteered for the study. Each interviewed a patient and observed a videotaped interview as part of the course. Each was randomly assigned to the order in which the two examinations were taken and randomly assigned to examiners so that each examinee was tested by two different examiners. Each test situation lasted approximately one hour and was scheduled a week apart. Candidates were informed that the examination using the live patient interview format

Presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

At the time this work was done, Dr. Naftulin was Associate Professor of Psychiatry, Dr. Wolkon was Associate Professor of Psychiatry (Psychology), Mr. Donnelly was Instructor in Psychiatry (Psychology), Dr. Burgoyne was Assistant Professor of Psychiatry, Dr. Kline was Associate Professor of Psychiatry, and Dr. Hansen was Associate Professor of Pediatrics and Psychiatry (Child), University of Southern California, Los Angeles, Calif. Dr. Naftulin is now in private practice at 9911 W. Pico Blvd., Suite 1270, Los Angeles, Calif. 90035.

would be conducted according to ABPN methods and scored using ABPN criteria. The examiner met the patient and had his or her chart available for study before the examinee interviewed the patient. Examinees were also informed that because ABPN was considering a videotaped interview format as a possible means of conducting future examinations, such an examination procedure would be included in the course.

Examiners

Four full-time academic psychiatrists served as examiners. All had examined psychiatrists on Part II of the ABPN examination at least once before and had conducted simulated oral examinations for residents and colleagues using the ABPN format. In our study two examiners conducted 12 interviews, one conducted 13, and one conducted 19. On one day the examiner tested the candidates after they viewed videotapes; on another day the examiner tested different candidates after they interviewed a patient.

Examiners used the ABPN pass, condition, or fail criteria in scoring both the videotaped and the actual patient interview. They were provided with an additional evaluation form for each test condition. An abbreviated version of the American Board of Orthopedic Surgery's 4-item interpersonal skills instrument (12) was used in the patient interview situation, and an item checklist of 10 topics on which the candidate was assessed was developed for the videotaped test situation. Examiners viewed the videotapes ahead of time, agreed generally on the working diagnosis of the "patients," agreed on answers to the questions asked, but disagreed about the importance given to some topics covered by the instrument. Nevertheless, all agreed to use it. At the completion of the study each examiner was asked specific questions in order to compare his attitude about the two examination formats, and each examiner completed a subjective narrative of his experience with the study.

Patients

All of the patients who agreed to be interviewed by the examinees were hospitalized with psychosis, thought and/or affective disorders, or brain syndromes.

Videotaped Interviews

The videotaped presentations consisted of a real psychiatrist interviewing actors playing the role of a psychotic or a neurotic patient.[1] Two bearded young men in their late 20s played both the psychotic and neurotic roles.[2] The order of actor and the order of role were randomly assigned to the examinees. For example, each examinee observed a 10–12 minute interview of one actor playing the role of a psychotic or neurotic patient and was examined on what he or she observed. The examinee then viewed the other actor playing the second diagnostic role and was examined after that interview. To determine whether the examinee's performance was affected by his or her perception of the videotaped patient as a real patient or an actor, a random selection of 14 of the 28 examinees were told that the videotaped patients were actors. The other 14 examinees were not specifically told but led to believe that the interviews were of actual patients. At the conclusion of the videotaped interview examination, all examinees were told that the videotaped patients were actors.

Written Examination

Eight weeks after the videotaped interview examination, 15 of the 28 examinees responded to an 80-item multiple-choice instrument designed like APA's Psychiatric Knowledge and Self-Assessment Program and Part I of the ABPN examination. Most items were selected by means of an item analysis from a longer test administered to a similar group of psychiatrists the previous year.

FINDINGS

Videotaped Interview Examinations

The scores earned by the candidates on the videotaped interview examination did not significantly differ (according to two-tailed t test) as a function of the order in which the examinees observed the neurotic or psychotic patient roles ($t=1.23$), which actor played which role (neurotic, $t=1.22$; psychotic, $t=0.59$), or the order in which the examinees took the videotaped or live patient interview examination (neurotic, $t=0.31$; psychotic, $t=1.25$). The examinees' scores for the psychotic role interview were highly correlated with their scores for the neurotic one ($r=.85$). This result suggests that testing for both categories of patients is not necessary for this type of examination.

The performance scores of the examinees did not differ significantly as a function of whether they were or were not told that the patients were actors (neurotic, $t=1.12$; psychotic, $t=0.08$). Each examinee was asked if it would have made a difference in his or her performance had he or she been told that the patient was an actor and not an actual patient or vice versa. All examinees in both test conditions reported that believing the patient was either an actor or an actual patient would not have affected their performance. These findings indicate that it makes no difference in examination performance whether examinees are told that the patient in the videotape is real or an actor or actress.

Live Interview Examinations

After interviewing a real patient, each examinee was rated on an 8-point scale (12) by the observer-examiner in four areas: 1) ability to obtain a history, 2) ability to relate well to the patient, 3) ability to apply factual

[1]We are grateful to Warner Johnson, M.D., for his participation.

[2]We are grateful to Eric Berk and David Reynolds, Ph.D.

TABLE 1
Mean Scores Given by Examiners in the Real Patient Interviews

Criterion	Mean Score Given by Examiner				F	Significance
	1	2	3	4		
Ability to obtain a history*	4.75	4.63	5.50	5.86	2.32	n.s.
Ability to relate well to the patient*	5.63	5.00	5.17	5.86	1.04	n.s.
Ability to apply factual information in a clinical setting*	3.75	4.13	4.83	5.57	3.22	$p < .05$
Overall final rating*	3.13	4.25	4.67	5.86	8.32	$p < .001$
ABPN numerical score**	72.88	73.50	73.16	82.86	5.48	$p < .01$

*Rated on an 8-point scale: 1 = inadequate; 8 = outstanding.
**75 and above = pass; 74–70 = condition; 69 and below = fail.

information in a clinical setting, and 4) an overall final rating. Each examinee was also given an overall numerical score according to ABPN criteria (see table 1). The examiners did not differ on the ratings they gave in areas 1 and 2 listed above. However, examiners significantly differed on their ratings of areas 3 and 4 and on the ABPN ratings. Application of Duncan's multiple range test (13) on each of the three significant items indicated that one examiner (examiner 1) contributed most to the statistical difference (see table 1).

Videotaped Interview Examination Scores Compared with Others

The overall mean performance scores for the live interview and videotaped interview examinations did not differ significantly ($t=0.91$). However, the score an examinee earned on one of the examinations was of no help in predicting his or her score on the other examination. The correlation was not significantly different from zero ($r=.08$). Even when the numerical scores were categorized into pass, condition, and fail, we found no statistically significant relationship between the two examinations, despite 65% examiner agreement in categories of the examinations ($\chi^2=.23$).

The relationship among the test scores of the 15 psychiatrists who took the written as well as the two oral examinations was also not significant. The written and the live interview examination correlated ($r=.39$). The written and the videotaped interview examination correlated ($r=.09$).

Oral Examinations

After the videotaped interview examination, each examinee was asked whether the procedure was a useful learning experience and a useful testing experience. Twenty-four of the examinees (85%) said that it was a useful learning experience, and 23 (81%) said that it was a useful testing experience.

The examiners were asked to write comparative evaluations of the two interview examination methods. They said that the videotaped interview examination did not allow them to estimate the examinee's ability to establish rapport, relate to a patient, demonstrate interpersonal skills, and elicit relevant information. On the other hand, they also said that the standardization inherent in the videotaped interviews was obviously lacking in the actual patient interview.

The issue of examinee anxiety was raised in terms of both formats. In addition to expected test anxiety, the examinees suggested that psychiatrists who were not accustomed to being observed while interviewing might have undue anxiety in the patient interview format; they also suggested a number of obvious test preparation procedures. The examinees reported that the videotape format created specific anxieties because of its unique artificiality and because it did not allow the examinee the flexibility and discussion inherent in the traditional ABPN format.

One of the examiners suggested combining the videotape format with a written examination. This would have the advantage of being more standardized and less expensive than the traditional examination format. The potential advantages of the videotape format were spontaneously suggested by the examinees in this study. Their suggestions included systematically varying the complexity and ambiguity of the symptoms of the "patient" in the videotaped interview as well as matching types of patient to the subspecialty emphasis of the examinee.

Specific technical points raised by the examiners will not be mentioned here. The administrative confusion that can occur in the actual interview format, such as the patient's arriving late or not arriving at all and not being able to find an office for the interview, are eliminated or greatly reduced by using the videotape. One issue raised by the examiners was the relatively greater amount of preparation they needed in the standardized videotape format compared with what they perceived as more spontaneity and less preparation in the traditional ABPN format. The examiners also pointed out a related issue: examining with the videotape was more tedious and monotonous.

One examiner totally rejected the videotape format as a useful way to examine because of the above reasons. Another examiner, although not rejecting the videotape format outright, stressed the importance of the candidates being examined on the basis of patient encounter. A third examiner felt that both methods were fair and both were adequate tests for certification. He further stated he would prefer to examine in

the traditional manner but would prefer to be examined in the more standardized manner. The fourth examiner recommended the use of both formats in the total certification and recertification process.

DISCUSSION

Contrary to our predictions, the patient-centered and videotape-centered scores of examinees did not correlate positively. Further, contrary to ABPN claims (unsupported by published data) that written scores in the basic sciences not only effectively screen candidates but correlate positively with oral examination scores, our findings demonstrate no such correlation. In addition, neither the oral patient-centered examination scores nor the videotape-centered scores correlated with the written scores. These findings indicate that approximately the same performance scores are earned with a neurotic or psychotic patient after a videotaped interview and that examinees reported it would make no difference if the live or videotaped patient were real or an actor.

The lack of relationship between the videotaped interview examination and the traditional oral examination may be explained in terms of examiner variables and patient variables. Using real patients means that some examinees will interview "easy" patients and others will interview "difficult" patients, creating a major potential source of error in assessing the performance of a psychiatrist expected to show a minimal level of competence. This error could be corrected by standardizing the clinical test situation by means of the videotaped interview.

These data indicate that there are significant differences among examiners in their assessments of the candidates in the real patient interview examinations but that none existed in the videotaped interview examinations. Apparently, the experience the examiners had in actual and simulated ABPN examinations did not successfully establish standardized criteria for evaluating psychiatric performance. The low agreement among examiners about the importance of questions in the videotaped interview examinations may have led to a small amount of inconsistency. Thus in both types of examinations, but especially in the ones involving real patients, there is a need for improved standardized scoring procedures with experienced examiners well-trained in such procedures.

The examiners reported that it was easier to compare examinees using the videotape format than the live patient format because the standardization of the former reduced differences of actual patient selection and assignment. In addition, the standard list of questions reduced the possibility of gross error by the examiners. A list of standardized questions may also be useful in the real patient examination, but its appropriateness would be influenced by controlled patient variables if patients are selected by means of the current ABPN method.

IMPLICATIONS FOR RECERTIFICATION

Among medicine's responses to public concerns over accountability is an increasing effort to assure the clinical quality of its practitioners (14, 15). Recent efforts to assure clinical competence in psychiatry have included appeals for continuing education, certification, and recertification (16, 17). The small number of certified psychiatrists in comparison with other specialists has been sufficiently documented (18). Third-party payers, limited licensing proposals, salary differentials, and the inevitability of a national health insurance program will increase the rate with which psychiatrists seek certification and probably recertification. The ABPN joined 22 members of the American Board of Medical Specialties in a resolution to adopt recertification as a goal (19); it has also solicited APA component groups for positions on recertification. Although concerns about psychiatry's certifying procedures as well as droll personal experiences are well documented (16, 20–25), ABPN is to be commended for its openness in providing at least limited feedback to candidates concerning their performance and eliciting feedback from candidates as to how they perceived their "rite of passage." Since at least one study documents the perceptions of patients examined by candidates (26), it is hoped that future studies will systematically reflect candidates' perceptions of their examination experiences and that such perceptions will be compared with candidate performance.

Board-eligible and Board-certified psychiatrists—satisfied, dissatisfied, or apathetic with ABPN procedures—deserve an informed method of assessing the ability of their assessors to assess them. In an era of increasing concern over accountability, the Board must increase its accountability to colleagues eligible for certification and to those diplomates soon to be recertified. Clinical competence levels must be made explicit, examination procedures standardized, and examiners better trained to examine for designated skills and knowledge among colleagues. Correlations must be established among different test methods (written examinations, videotaped interview examinations with real patients or actors, and actual patient interview examinations) before one method can sufficiently replace or complement another in a meaningful way. Findings from this study indicate that such correlations are not significant.

Recertification provides one path psychiatry can take in its efforts to assure quality care for patients. However, findings from this study suggest that the means by which certification and recertification are to be achieved remain a persistent challenge for psychiatry in the United States.

Platelet MAO Activity in Schizophrenia and Other Psychiatric Illnesses

BY JOHN SULLIVAN, M.D., CHARLES N. STANFIELD, AND CHARLES DACKIS, M.D.

Previous reports have indicated that platelet MAO activity is low in some schizophrenic and other psychiatric patients. However, other studies have not been able to replicate this phenomenon. This study supports the previous observations of low enzyme activity in some chronic schizophrenic patients. The authors discuss the thesis that low platelet MAO activity may be a biochemical marker for vulnerability to psychiatric illness.

THE RELATIONSHIP between low platelet MAO activity and psychiatric illness in general and schizophrenia in particular continues to interest many behavioral scientists and clinicians. Since Murphy and Wyatt's 1972 report (1) of lower platelet MAO activity in 33 chronic schizophrenics than in 22 controls, 14 follow-up studies have appeared in the literature. Seven of these confirmed Murphy and Wyatt's observation of low platelet MAO activity in some schizophrenic patients, whereas the other 7 studies failed to demonstrate a significant difference in enzyme activity in schizophrenic patients.

The first follow-up study (2) to confirm the findings of the initial report showed that the mean MAO activity of both schizophrenic and nonschizophrenic twins in 13 monozygotic pairs was significantly lower than that of 23 nonpsychiatric controls. Because drugs, diet, and environmental factors at the time of blood sampling could not readily explain the decreased MAO activity in twins discordant for schizophrenia and since platelet MAO activity is under genetic influence (3), Wyatt and colleagues (2) concluded that low platelet MAO activity might provide a genetic marker for vulnerability to schizophrenia. Meltzer and Stahl (4) subsequently reported that platelet MAO activity in 12 chronic schizophrenic and 10 acute schizophrenic patients was significantly lower than that of 15 normal subjects. Nies and associates (5) also showed that platelet MAO activity was significantly lower in 12 schizophrenic patients than in 12 normal subjects. In addition, these authors, like Meltzer and Stahl, noted that the choice of substrate was critical to the demonstration of a difference in enzyme activity.

In 1975 Zeller and associates (6) reported low platelet MAO activity in a large group of schizophrenic patients compared with nonpsychiatric controls. On the basis of different substrate affinities between the MAO from the schizophrenic patients and controls, Zeller and his group suggested that the platelet enzyme was structurally different in the schizophrenics. Two additional reports of low platelet MAO activity appeared in this journal. Domino and Khanna (7) studied 13 male chronic schizophrenic patients who had not received psychoactive medication for at least six months before evaluation. Schildkraut and associates (8) identified a subgroup of schizophrenic patients characterized by low platelet MAO activity, auditory hallucinations, and paranoia. In a recently published study demonstrating reduced platelet MAO activity in schizophrenic patients, Murphy and associates (9) could not show parallel reductions in the activities of other platelet enzymes (including succinate dehydrogenase, cytochrome C reductase, and lactate dehydrogenase), thus suggesting that the reduced MAO activity could not be explained by nonspecific platelet changes.

To our knowledge, the first report that failed to confirm Murphy and Wyatt's observation of reduced platelet MAO activity in schizophrenic patients appeared in this journal in 1974 (10). Although Friedman and colleagues did not find a difference in platelet MAO activity in this study of 26 schizophrenic patients and 23 nonpsychiatric control subjects, they did discover a tendency toward lower MAO activity in the schizophrenic group; this tendency was more marked in the women. Similarly, Shaskan and Becker (11) were unable to demonstrate reduced platelet MAO activity in 24 schizophrenic patients compared with 15 controls. These investigators found a bimodal distribution of MAO activity in the nonpsychiatric subjects and alcoholics used as controls as well as in the schizophrenic patients. A more recent study (12) of 680 nonpsychiatric subjects demonstrated a unimodal frequency distribution of platelet MAO activity, and 2 other recent studies (13, 14) have also shown

Dr. Sullivan is Senior Physician, Psychiatry Service, and Mr. Stanfield is Research Assistant, Research Service, Veterans Administration Hospital, 508 Fulton St., Durham, N.C. 27705. low platelet MAO activity in patients with alcoholism. Therefore, as Murphy and Wyatt have suggested, sampling and technical difficulties may have influenced the findings of Shaskan and Becker (11).

A study by Carpenter and colleagues (15) also failed to demonstrate a difference in enzyme activity between 44 acute schizophrenic patients and 131 nonpsychiatric controls. However, it should be noted that studies of adopted-away children of schizophrenic patients (16) suggest that acute and chronic schizophrenia are different illnesses. Takahashi and associates (17) reported similar platelet MAO activity in "33 schizophrenic patients . . . newly admitted . . . who had never been treated with psychoactive drugs" and in "50 normal control subjects" with lower platelet MAO activity in "43 . . . chronically ill schizophrenic patients . . . on . . . various phenothiazines." Three additional studies failed to show significantly lower platelet MAO activity in chronic schizophrenic patients. In two of these studies (18, 19) the schizophrenic patients were receiving conventional doses of neuroleptic medication; in the third study (20, 21) they had not been treated with antipsychotic medication for at least six months.

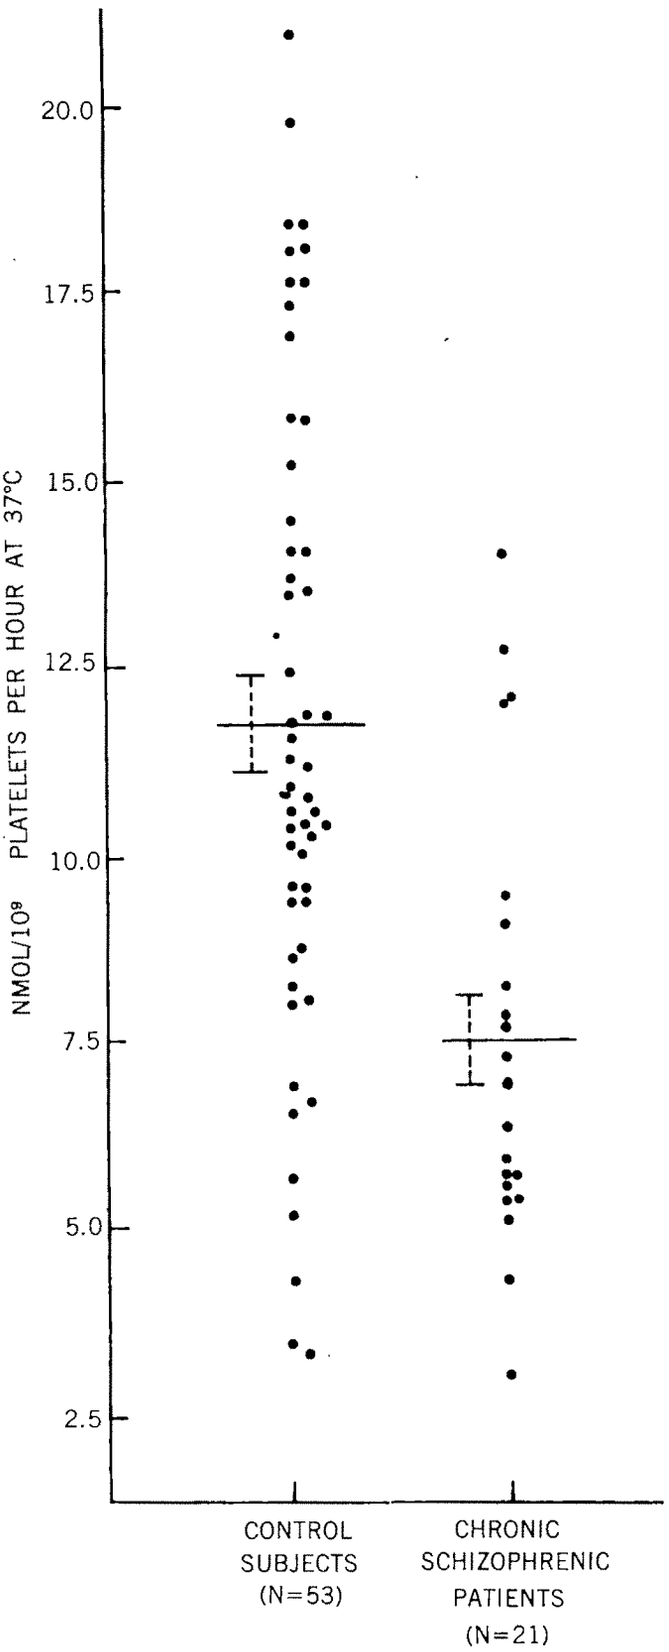
Thus the present literature on platelet MAO activity is interesting and suggestive of a link with some psychiatric illnesses, but it leaves many questions unanswered. We will therefore present additional data and theoretical inferences that may prove useful in delineating the relationship between platelet MAO activity, schizophrenia, and other psychiatric illnesses.

METHOD

The control group consisted of 53 men between 21 and 59 years of age (mean = 38.8, SEM = ± 2.0) who were selected from surgical patients hospitalized at the Durham Veterans Administration Hospital for herniorrhaphy or hemorrhoidectomy (N=39), Veterans Administration personnel (N=6), and Duke University students (N=8). None of these individuals gave a history of past medical or psychiatric illness. Some of the surgical patients were taking a benzodiazepine for sleep. Otherwise, there was no history of drug use in this group.

The 21 schizophrenic patients in the study were male veterans, between the ages of 21 and 51 years (mean = 31.1, SEM = 1.8), who were hospitalized on the psychiatry service with a diagnosis of chronic undifferentiated schizophrenia or paranoid schizophrenia over the same time period as were the surgical patients. All of the psychiatric patients were evaluated by a first-year psychiatric resident and by a Board-certified senior staff psychiatrist. Additional information was obtained on the psychiatric patients from social workers and ward psychiatric nurses. All of the schizophrenic patients admitted to the study met the *DSM-II* criteria (22) for chronic undifferentiated schizophrenia or paranoid schizophrenia as well as Feighner and associates' criteria for schizophrenia (23). Each of these patients had been hospitalized from 3 to 18 times over a period of 3–26 years. Some of them were also taking a benzodiazepine for sleep. However, there was no past or present history of alcoholism, drug abuse, organic brain syndrome, or chronic medical illness. All of the patients gave a history of taking neuroleptic medication in a dose range equivalent to 400–1700 mg of chlorpromazine. Informed consent was obtained from all of the subjects after the nature of the study had been fully explained.

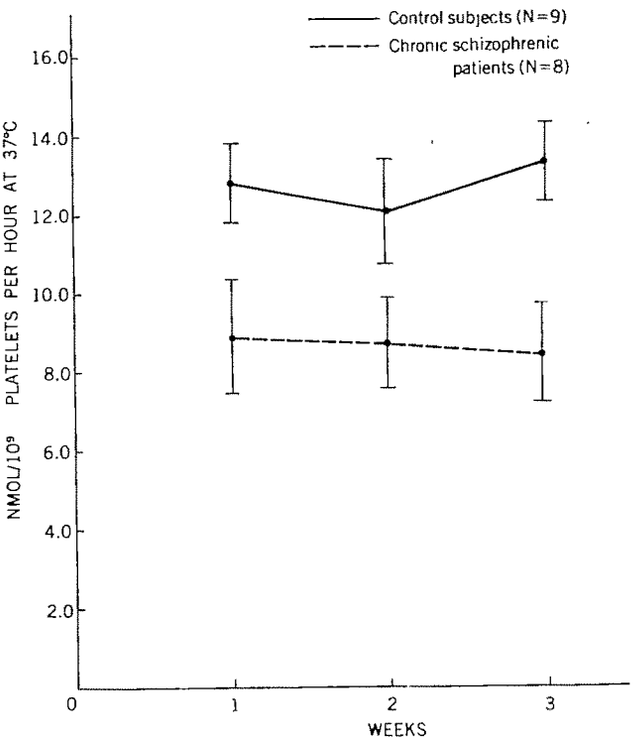
None of the control subjects or schizophrenic subjects demonstrated abnormalities on peripheral blood smear, red blood cell count, hematocrit, hemoglobin, mean corpuscular volume, mean corpuscular hemoglobin, or mean corpuscular hemoglobin concentration. Physical examination revealed no evidence of dermatitis or peripheral neuropathy. These criteria were included in the protocol because iron-deficiency anemia (24) and riboflavin deficiency (25) have been associated with low platelet MAO activity.



Venous blood samples (18 ml) were collected for platelet MAO activity determinations, and platelet pellets were prepared by sequential centrifugations of platelet rich plasma (PRP) samples obtained during the first week of hospitalization. Some of the platelet pellets were frozen from several days to a week at −80°C so that enzyme activities from subjects of both the control and schizophrenic groups could be measured at the same time. Previous work in our laboratory has demonstrated that freezing the pellets from several days to six weeks results in negligible loss of enzyme activity. Platelet counts were determined on PRP aliquots using a standard electronic particle counting procedure (Coulter Electronics Thrombocounter, Curtin Matheson, Atlanta, Ga.).

Washed platelet pellets were homogenized in a Thomas grinding vessel and distributed as .05 ml aliquots containing .2–.5 mg of protein. The aliquots were incubated with tryptamine, prepared from tryptamine bisuccinate, side chain $-2-^{14}C$ (New England Nuclear), and tryptamine HCl, at a final concentration of 7×10^{-5} M in .08 M phosphate buffer, pH 7.2. The reaction was terminated by addition of HCl, and the product was extracted into washed toluene. Product formation was assessed by liquid scintillation spectrometry (Intertechnique Model SL 30) using external standards. Phosphate buffer was used instead of protein for the blanks. The reaction was linear for both time and platelet count within the dimensions of the assay. Method and sample variation (calculated as the difference between paired samples divided by their mean) was ±4% for duplicate samples from the same specimen. Additional details of the assay procedure have been published elsewhere (26).

RESULTS



As demonstrated in figure 1, mean platelet MAO activity for the chronic schizophrenic group was 7.7±.7

FIGURE 1
Platelet MAO Activity in Chronic Schizophrenic Patients and Control Subjects*

*Mean activity was significantly lower in the schizophrenic patients ($p<.001$).

FIGURE 2
Mean Platelet MAO Activity in Chronic Schizophrenic Patients and Control Subjects over a Two-Week Period

nmol/10^9 platelets per hour (mean±SEM) and 11.7±.6 nmol/10^9 platelets per hour for the controls. Thus mean platelet MAO activity was 34% lower in the schizophrenic group ($p<.001$, two-tailed t test). The platelet count for the schizophrenic group was $2.85\times 10^8\pm.15$ (mean±SEM) and was not significantly different from the platelet count for the control group ($2.90\times 10^8\pm.18$). Figure 2 shows that the mean platelet MAO activity values were relatively stable over a two-week period for both the schizophrenic and control groups. (Due to technical limitations in the laboratory and attrition, only 9 control subjects and 8 schizophrenic patients were followed.) The mean intrasubject coefficients of variation for the schizophrenic subjects (17.1%±3.3%) and the control subjects (16.0%±2.6%) were within experimental error.

DISCUSSION

The low platelet MAO activity observed in the chronic schizophrenic patients in this study is consistent with the seven previous reports of low enzyme activity in some schizophrenic patients and lends additional support to the validity of Murphy and Wyatt's original observation (1). The results of our study cannot be explained by differences in race or sex, and age does not appear to be a significant variable. Although the schizophrenic subjects were significantly younger

than the control subjects (3.1±1.8 years versus 38.8±2.0 years) ($p<.05$, two-tailed t test), the study by Robinson and associates (27) on the effects of aging on platelet MAO activity showed a gradual increase in platelet monoamine oxidase activity in men after the age of 45.

Two subsequent studies (12, 21) failed to show a correlation between platelet MAO activity and age. Diet, activity, and the effects of hospitalization also do not appear to be significant variables in that the mean enzyme activity of the schizophrenic subjects was still significantly less than that of the 39 surgical patients (7.7±.7 versus 12.0±.7, $p<.001$, two-tailed t test). Drug effect is also an unlikely explanation for the low platelet MAO activity observed in the schizophrenic subjects. Although there is some evidence that neuroleptic medication has a slight inhibitory effect on MAO activity in vitro and in vivo (17, 28), other investigators have demonstrated increased MAO activity after treatment with neuroleptics (21). There is also a report in the literature (9) that 10-fold to 1,000-fold higher drug concentrations are required for in vitro MAO inhibition than are obtained in plasma during treatment with neuroleptic medication. There is ample additional evidence to suggest that the low platelet MAO activity observed in some schizophrenics is not merely drug effect (2, 7, 29).

These observations are particularly interesting in light of reports that some patients with bipolar affective illnesses (30, 31) and alcoholism (13, 14) demonstrate low platelet MAO activity. Severely disturbed manic-depressive subjects are often clinically indistinguishable from schizophrenic subjects, particularly paranoid schizophrenics (32, 33), and alcoholism has been associated with both schizophrenia (34) and manic-depressive illness (35). Thus low platelet MAO activity may be associated with several forms of psychiatric illness. Buchsbaum and colleagues (36) have provided further support for a relationship between low platelet MAO activity and psychiatric illness. They found that probands with low enzyme activity in a population of 375 college student volunteers had 8 times the incidence of suicide or suicide attempts in their families as well as twice as many psychiatric problems as did subjects with high enzyme activity. These authors therefore suggested that low platelet MAO may predict vulnerability to psychiatric disorder.

Although it is possible that low platelet MAO activity reflects low MAO activity within the central nervous system, the relationship between platelet MAO and brain MAO remains problematic (37). As with reports on the platelet enzyme, reports on regional brain MAO activity in schizophrenia are contradictory. There are two reports in the literature of low regional brain MAO activity in schizophrenics (38, 39) and four statements of normal regional brain enzyme activity in schizophrenics (40–43).

Another important issue is the role of genetics in the low platelet MAO activity observed in some psychiatric patients. As previously discussed, Wyatt and associates proposed, on the basis of their twin study (2), that platelet MAO activity may provide a genetic marker for vulnerability to schizophrenia. Zeller and associates' data (6) suggested that the platelet MAO of the schizophrenic subjects they studied was different structurally from that of their nonpsychiatric controls. Our finding of stable platelet MAO activity over 2 weeks in both the controls and the schizophrenics is consistent with Murphy and associates' observations (12) of controls and psychiatric patients over 8–10 weeks and implies that platelet MAO activity is a relatively stable characteristic of the individual. In addition, previous work (3) has shown that platelet MAO activity is under genetic control. Therefore, low platelet MAO activity may provide a genetic marker for vulnerability to psychiatric illness. The clinical expression of the mental illness could result from the interplay between the degree of penetrance of the genetic lesion and psychosocial factors.

However, the substrate and enzyme kinetic studies of other investigators (9) argue against an alteration in the active site of the enzyme, and another group of researchers (44) could not demonstrate a difference in electrophoretic patterns of platelet MAO in chronic schizophrenic subjects, manic-depressive subjects, and nonpsychiatric controls. Additional physicochemical, animal, and clinical studies are necessary to delineate whether the low platelet MAO activity observed in some patients with psychiatric illness reflects primarily a genetically determined structural abnormality of the enzyme or another factor such as a more fundamental biochemical alteration, changes in the lipid environment of the enzyme (45), enzymatic inhibition, changes in the synthesis or degradation rates of MAO (46), psychosocial factors, or chronicity of the illness.

Another promising approach suggests that the low platelet MAO activity in schizophrenics and other patients with psychiatric illness results from immunological factors. For example, some studies have demonstrated in vitro morphological transformations of lymphocytes from schizophrenic patients, suggesting antibody production (47). Other investigators have reported antibodies to brain protein and lymphocytes in schizophrenics (48). There are also reports of low activity of leukocyte oxidative enzymes (including MAO) isolated from schizophrenic subjects, and supplementary animal experiments suggest that these low enzyme activities result from immunological changes (49, 50). We have also recently typed lymphocyte MAO, using multiple substrates and inhibitors, and found it identical to platelet MAO. In addition, we have demonstrated a decrease in lymphocyte MAO activity in the same schizophrenic subjects who demonstrate low platelet MAO activity (unpublished data, from Sullivan and Stanfield). Thus the low platelet MAO activity observed in some patients with psychiatric illness may result from immunopathological factors.

Foundations' Fund Prize for Research in Psychiatry

The Board of Directors of the Foundations' Fund for Research in Psychiatry has made a grant of $30,000 to the American Psychiatric Association for the establishment of an annual Foundations' Fund Prize for Research in Psychiatry.

Candidates for the prize must be citizens of the United States or Canada and must be nominated by a sponsor. Sponsors must be members of the American Psychiatric Association. Members of the prize board are excluded from submitting nominations.

The sponsor should submit a supporting letter justifying in detail the nomination and summarizing the research accomplishments of the nominee.

The nominee should submit the following:

1. an up-to-date curriculum vitae
2. an up-to-date bibliography
3. a group of representative and thematically linked papers or books published (or accepted for publication) that are in English and dated within 10 years of the deadline for submission
4. a summary statement written by the nominee that emphasizes the principal theme (or themes) of the work and its internal cohesiveness and consistency

Six copies of each entry should be sent to Joel J. Elkes, M.D., Chairperson, Foundations' Fund Prize for Research in Psychiatry Board, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but cannot be returned. The deadline for submission is December 1, 1977. Any entry received after that date will be automatically entered for consideration for the 1979 award unless withdrawn by the nominator or candidate.

A Psychodynamically Oriented Group Training Program for Early Childhood Care Givers

BY STANLEY I. GREENSPAN, M.D., BARBARA SILVER, PH.D., AND MARTIN G. ALLEN, M.D.

A training program for enhancing the care-giving qualities of child-care workers was developed and implemented through semistructured groups for family day-care mothers. The authors describe the theoretical orientation, program goals, and the outcome for trainees and trainers. Most impressive was the group process and content, which indicated the effectiveness of a psychodynamically oriented program for care givers—people who ordinarily would not be expected to integrate such an experience successfully.

THIS PAPER describes a unique training program for family day-care mothers—a group of women who are becoming an increasingly important source of care givers for children. These women take care of a small group of other people's children, especially the children of working mothers. Of the six million children under six years of age who have working mothers (1), 31% are cared for in someone else's home (2).

Preliminary investigations have led to optimism about the quality of care in family day-care arrangements and the potential for further development of this resource (3–6). However, there is no direct means of learning about the quality of this care or the usefulness of training day-care mothers to facilitate the total development of the children because each care giver, in a sense, conducts a private business in her own home.

An experimental training program that employed a dynamic developmental perspective was conducted in an attempt to learn more about family day care and to enhance the capacities of family day-care workers. The purpose of this program was 1) to learn more about family day-care mothers through their participation in small, semistructured groups, and 2) to enrich their understanding of children, thereby perhaps changing some of their routine patterns of child care.

Dr. Greenspan is Chief and Dr. Silver is Research Psychologist, Mental Health Study Center, National Institute of Mental Health, 2340 University Blvd. East, Adelphi, Md. 20783. Dr. Allen is Assistant Professor of Psychiatry, Georgetown University Medical School, and Director of the Group Therapy Program, Department of Psychiatry, Georgetown University Hospital, Washington, D.C.

The main goal of the training itself was to develop the capacity of the family day-care worker to facilitate the emotional growth of the children in her care. Specifically, the purpose of the training was to enhance the day-care mother's capacity to 1) perceive what the child is communicating (accurate perception of what the child is communicating will facilitate the development of his reality testing), 2) understand empathetically, but not overidentify with, the child's emotional experience (an adult's balanced understanding of what the child is feeling, as well as the child's own emotional experiences, enhances the child's sense of trust and security), 3) respond temporally in an effective way to the child's behavior (feedback to the child about his behavior is important in helping him establish a sense of inner control and internal boundaries), and 4) respond flexibly to the child's behaviors (flexible and sensitive differential responses to a child help develop a sensitive and differential repertoire of coping mechanisms).

A second goal of the program was to learn whether a relatively untrained person in the mental health field could, under professional supervision, conduct the training experiences for the family day-care workers. If so, the training program would have the potential for broader use and would be economically feasible.

Two groups were formed; each was led by a relatively untrained social service worker under supervision. Whereas training programs for such groups have usually been oriented toward didactic presentations, the present program was more psychodynamic in orientation. The focus was to be on understanding and openness in communication, discussion of child-care problems shared in common, and the expression of feelings. This method approaches the model of group therapy with day-care mothers verbalizing, sharing, and delineating the specific emotions and concerns that are involved in their understanding of and response to the children. The group leaders focused on both the content and the process of the group. The content provided useful examples of adult-child situations for discussion. The group process enabled the day-care mothers to explore together their mutual and individual concerns. The leaders were to highlight feelings, conflicts, defensive patterns, and alternate means of coping.

THE TRAINING GROUPS

The group members selected were the first 16 women who responded to a letter of invitation sent out by the local department of social services. (There were 35 responses to 200 invitations.) The letter stated only that there would be an opportunity to meet with other family day-care mothers for seven 1½-hour sessions to discuss their common concerns. Each group originally consisted of 8 women with socioeconomic status designations of lower middle-class and below. There were both black and white day-care mothers, and they ranged in age from 23 to 50 years. At the first session 1 group lost 2 women; 1 never came and 1 dropped out.

TRAINING AND SUPERVISION OF GROUP LEADERS

In the supervisory sessions the 2 leaders were instructed to 1) attempt to sensitively understand what was being said, 2) facilitate discussion of themes by rewording discussions, 3) pose questions that would further develop a theme, and 4) highlight the theme when it seemed to emerge only in fragments. In general, the leaders were to encourage members to speak out about what was on their minds and to promote development of these ideas. The leaders were not to direct or suggest issues for discussion.

In order to facilitate group discussion, a number of techniques were stressed. The leaders were instructed to move between process and content, look for affect within the group, stress the differences between stereotyped and flexible ways of dealing with stressful situations, move between the adult and child world, and move between relationships within and outside the group.

In addition to learning the principles of group leadership, both leaders were helped to understand and cope with their own emotional struggles. The main issues were their initial feelings of suspicion and helplessness, tendencies to deny or cover up their own emotions as stimulated by the groups, and to use certain defenses, the most prominent of which was boredom. A parallel was drawn between the feelings they experienced in relation to the group and the feelings the family day-care workers experienced in relation to the children they cared for. The supervisors held the view that this experience would be productive for all concerned.

One of the leaders began her experience with mixed feelings; she was suspicious of any approach that focused so substantially on emotions, denigrated the day-care workers, and felt bored. Yet, by the end of the program she felt a part of the group, looked up to some of the women as mother figures, and manifested a sincere, warm regard for them. The second leader initially had warm, positive feelings toward the people with whom she was to work. However, due to her personality, she was less able to tolerate expressions of emotion, attempted to keep the group focused on concrete issues, and often felt overwhelmed.

DEVELOPMENTAL SEQUENCE OF THE GROUP SESSIONS

Without the motivation of psychic pain or symptoms, a number of day-care mothers were able to form two training groups that developed features similar to those of short-term treatment groups; that is, from a period of initial reserve there evolved cohesion, identification, open expression and examination of feelings, capacity to deal with anger, and finally, the experience of the separation process. For the sake of brevity, we will provide only a combined summary of both groups' thematic progression.

The initial sessions dealt with a number of issues generally common to beginning groups, e.g., factual data regarding members' identities, what the tasks ought to be, and inquiries about the role of the group leaders. This exploratory phase quickly yielded to more specific discussions about the responsibilities of real versus day-care mothers, what characterizes a "bad" parent, and how one deals with "problem" children. The issue of problem children dominated the early sessions, with the day-care mothers citing many examples.

For instance, one woman described her problem with a passive, withdrawn, negativistic boy who clung to her and would not sleep at naptime. She was aware that the boy's father frequently beat him at bedtime, yet she did not know how to use this information to help the child. Instead, she found herself torn between being either overindulgent or minimally nurturing. At times she felt sorry for him and at other times angry because he was "such a pest." The group wisely advised her to provide the boy with alternative activities when he was demanding and to give him her full attention when she felt relaxed and could spare the time. Another day-care worker's problem with twin brothers who would not separate from each other and whose behavior made her "anxious" led to a discussion of how one stimulates a sense of trust in children when there appears to be little or none. At one session the issue of trust was discussed at such length as to imply that what was actually being dealt with indirectly was how to develop trust among the members of this new group.

What came through clearly from almost the first session was the annoyance the women experienced when their routines were inevitably interrupted. It was apparent that they were at times rigid and inflexible in many "problem" situations.

In the first two sessions the quality of interaction was one of polite acceptance of each other, with the expected initial emotional reserve. Surprisingly, there was also an acceptance of the leader's relatively restrained role of facilitator, rather than active intervenor. By the third and fourth sessions the facilitator

noted the growth of a melding process, which became more apparent at each session. As the members of both groups became more emotionally open, the depth of the content began to match this growing emotional accessibility. Talk focused on problem children, as well as the problems created for those who care for other people's children. For instance, many of the day-care mothers worried about what to do when a child was injured and how to deal with the natural mother. Should the caretaker act immediately without first contacting the parents and thus risk being sued, or should she delay until they could be notified? This very real problem highlighted an important affective concern for substitute mothers, that is, their relationships and feelings toward the natural mothers. Hints of competition and rivalry between care givers and real mothers emerged, as well as reaction formations and guilt feelings against these feelings.

During the first and last of the seven sessions, both groups completed a projective test that contained a number of items dealing with the vicissitudes of sexuality and aggression in children. Discussions about these items in the middle sessions led to some interesting exchanges, parts of which could only have been elicited from groups whose members were becoming more open and supportive toward each other. For example, they were able to talk about what constituted masturbation and to question its appropriateness in young children. When menstruation was discussed, the members felt able to express themselves freely enough to state beliefs such as that of one strong-minded woman who claimed that "male nosebleeds are the counterpart to menstruation and could lead to sterility." Another topic was the appropriate time for toilet training and some of the problems encountered during this process. A major concern centered on the discontinuity encountered between the care giver's own procedures and beliefs in dealing with children and those of the natural parents, and the effect on the children.

In one revealing and emotional session, a mother described a 5-year-old boy in her care as having "effeminine [sic] likes" and "wanting to pull down the pants of my young son." When she asked him what he was doing, he claimed to "want to put a stick in his rectum." With this disclosure the group's anxiety rose to a level that precluded much response from the other members. However, there was notable continuity between this meeting and the next, when the woman who at an earlier session had related her beliefs on nosebleeds and menstruation now offered her views on identifying the homosexual child. She stated emphatically that "a child should be turned upside down and if the child has a vagina, rectum, and penis, the child is a homosexual." This time the women were able to respond actively, despite the high level of anxiety that surfaced. Some agreed with the "theory" presented, while others found it amusing, although their amusement had a nervous quality to it. The ensuing discussion permitted an exploration of both the facts regarding children's sexuality and the feelings that children's sexuality generates in adults. The spectrum of adult defenses, from denial to exaggerated interest, was exposed.

There was another interesting development at the same time. The women who had related some of their experiences with problem children in earlier sessions said that these children now seemed to be less difficult. For example, the twins were playing with other children, and the clinging, withdrawn, negativistic boy was less tense, more outgoing, and more flexible. However, the women were unsure as to why the children were doing better. There were also references to their own decreased anxiety and the helpfulness of the groups' suggestions.

Although the groups were racially mixed, the issue of race did not surface until the middle session. A black woman, in reporting that her son's jacket had been stolen in school, implied that the theft had racial connotations. The women then shared their personal experiences with racism, although at no time was the racial composition of the groups mentioned directly. Most of these women took care of a racially mixed group of children, and they talked about the stresses and rivalries among the children, but also some of the benefits to themselves and the children in a changing society.

At one point during these same sessions a woman became openly irrational, voicing suspicions about the social service system, her inability to trust a neighbor, and her belief that at times people followed her and were "after her." She attempted to dominate the group by yelling at some of the other members. The women responded to all of this reassuringly, for the most part minimizing the woman's irrationality and at times even ignoring it. It is important to note that there was a sense of comfort and security in the group as a whole and that the group members did not become fragmented by this disruptive behavior. The following week the woman appeared more intact, and she spoke about her concerns in a more reasonable fashion. There were no signs of the suspiciousness or open hostility and anger of the previous session. In talking about herself, she claimed that for some reason she was feeling more relaxed than she had the week before.

With only two sessions remaining, separation concerns emerged in one group. One of the women told of a natural mother who did not want to separate from her daughter when the child was brought to the care giver's home. A discussion ensued about the effects on children of separation from their families and the effects of separating a child from his or her mother. The women talked about becoming attached to the children in their care and their feelings at having to separate from them. This exchange appeared to result in the development of a feeling of empathy for the natural mothers, as well as a useful exploration of the women's own feelings of attachment, dependency, and separation.

Issues of separation and termination were dealt with

formally in the final session. The members of both groups expressed their high regard for the leaders, and they agreed that the experience had been very useful. There were also covert indications of anger toward authority figures and talk about doctors who are not always helpful. Both groups showed resistance to completing the projective test again, although most finally agreed to do so. However, two women staunchly refused to comply, and the groups supported their continued resistance. Many of the participants indicated their wish to meet on their own, and they talked about sharing equipment and joining together for trips. Much care was taken to exchange telephone numbers, and there were many promises to keep in touch with each other.

ASSESSMENT OF THE GROUP EXPERIENCE

The following four measures were used to assess the groups' functioning: analysis of the groups by the supervisors, subjective assessment of the group members by the group leaders, self-assessment by the day-care mothers, and assessment by the use of a projective test developed specifically for this project (7).

When the two group leaders were asked to rate the women on a scale from 0–5 in relation to the degree of positive change, they gave 9 of the 14 women scores higher than 3.

The self-ratings of the group members were positive. They said that the group experience resulted in the "improvement of problem kids," "the exchange of ideas," and "new ways to help kids," and they referred to a sense of group identity. While their positive reports were subjective, they were interesting since traditionally this population responds to "training" with apathy.

Recorded in terms of pregroup and postgroup experience, the individual response pairs on the projective test items were rated equal 57% of the time (that is, there were no qualitative differences in the response before and after the group sessions). When the pairs were rated unequal, the postgroup responses were rated better in a ratio of 2 to 1.

DISCUSSION

Three findings need to be emphasized. The first was the day-care mothers' wish for help and their reports that they had benefited from the group and that there were positive changes in some of the children for whom they cared. Often, however, it was not clear what aspect of the group experience had been helpful. It was felt that the day-care mothers' guilt, anger, or feelings of helplessness about a child's negative behavior inadvertently reinforced the behavior. This inadvertent reinforcement occurred because feelings of anxiety or helplessness led the care giver to respond in a stereotypic or insensitive manner, which, in turn, further increased the child's frustration, provided attention for his maladaptive behavior, or set up expectations for the continuation of the behavior. Verbalizing her feelings and being in a setting where her concerns could be aired decreased the day-care mother's anxiety and permitted her to think and respond more flexibly and autonomously. Although there were times when specific recommendations were helpful, these incidents did not appear to be as impressive as the nonspecific group effect.

The second finding related to the day-care mothers' openness and ability to use a semistructured setting. Discussions of anger, dependency, sexuality, and separation highlighted the usefulness of a semistructured, psychodynamically oriented group setting. It is questionable whether such material would have emerged and been worked with in a more structured setting. Verbalization of this material permitted factual correction when appropriate. More important, shared concerns and anxiety could be usefully explored and a general tolerance for "feelings" and capacity for balanced empathy reinforced.

The third finding was the groups' cohesiveness. Wishes for communal trips, shared equipment, and so forth indicated a deep level of a sense of belonging that cannot be underestimated in jobs where adult-adult contact is minimal. In this context it is important to note the "process" that occurred in the groups; some initial anxiety and distrust gave way to a series of sessions in which primitive and affectively laden material was worked on. Subsequently, there was an indication of some aspects of a termination process.

The high degree of motivation of the family day-care mothers was an impressive finding. Usually, when there is no obvious extrinsic motivation (e.g., financial gain), voluntary participation by members of lower and lower middle class socioeconomic groups is poor. The importance of mobilizing interest and curiosity rather than passivity in any type of training program cannot be overemphasized.

An additional outcome was the indication that under supervision, people relatively untrained in mental health can lead such groups. The use of group leaders who had not had formal mental health training has important financial implications in making such programs feasible. However, it is necessary to be selective about the characteristics that group leaders should possess, e.g., openness, warmth, and a reasonable level of psychological maturity.

Some liabilities of this type of group experience should also be considered. In a relatively unstructured group setting there is the possibility that a high degree of stress may be created in the group leaders and members. In these training programs one group leader who was under much personal pressure experienced an added strain in leading a group.

Although none of the day-care mothers in the present study appeared unduly stressed, the effects of verbal attacks or regressive emotional experiences must be considered. Members' ego strengths, skills of the

group facilitators, and the quality of supervision all play a part in determining to what extent certain group experiences will have deleterious or positive results.

In summary, this report has been an attempt to develop a picture of what these groups were like for the family day-care mothers and the group leaders and of how the training experience was used. It is hoped that additional investigations will continue to explore this area.

Anger and Fear

BY HOSSAIN B. DANESH, M.D.

The author proposes that fear and anger are innate defensive mechanisms mobilized by perceived threats to the individual. Both mechanisms are accompanied by anxiety and an urge to escape or attack. The individual's lifestyle, which is the result of interaction between his innate qualities and life experiences, determines whether he will attempt to deal with threats, his fear and/or anger, and the resulting anxiety in an objective or pathological manner. This formulation underscores the need to learn methods of coping with anger and fear from early childhood, so that they do not develop into pathological behavior patterns.

WE ALL get angry, but our understanding of the nature of anger differs considerably. The argument about the causes and effects of anger ironically finds its expression in the psychiatric literature through an avoidance of the term itself. Anger usually appears in camouflage under definitions such as aggression, violence, and hostility, or else is referred to almost casually and in passing, as though it is too simplistic for consideration. In a world in which "aggression" has become common property, in which "violence" is now a cliché, and in which "hostility" has been "cosmeticized" in entertainment and institutionalized through sports, it might be useful to approach the concept of anger and its influence upon us.

While we have all experienced the simple state of anger, it is clear from our clinical observations in psychiatry that the condition, Janus-like, contains a paradox. For although psychiatrists avoid the term itself in the psychiatric literature, they have succeeded in unearthing a cluster of avoidance techniques by which the phenomenon of anger manifests itself in the form of psychosomatic disorders, depression, destructive behavior including suicide and homicide, and interpersonal as well as family difficulties. Therefore if anger is not expressed and dealt with, it undergoes a subtle change and can subvert the creative functions of a human being not only through violence and hostility but through self-destructive and self-limiting conditions as well.

In order to review the interrelationship between these polarities and thereby reach a fresh definition of the phenomenon of anger, in this paper I will consider the major prevailing theories of aggression and will attempt to arrive at a pattern within which the fluctuating manifestations of anger, fear, anxiety, and aggression can be understood.

Dr. Danesh is Assistant Professor of Psychiatry, University of Ottawa, Psychiatrist-in-Charge, Adolescent Services, Royal Ottawa Hospital, 1145 Carling Ave., Ottawa, Ont., Canada K1Z 7K4, and founder and Consultant, Centre for Studies on Anger, Ottawa.

BACKGROUND THEORIES

Aggression and Violence

In the early decades of this century (whose wars have made anything experienced by previous decades seem insignificant), Freud (1) postulated that man was a creature at the mercy of his instincts, which were essentially of two kinds: life and death, love and hate, the sexual and the aggressive instincts. The former he named "eros" and the latter he described as "the aggressive instinct whose aim is destruction." Elaborating on this theory, he wrote that human instincts are "only of two kinds: those which seek to preserve and unite . . . and those which seek to destroy and kill."

The application of this theory finds itself aptly reflected in a scrap of significant correspondence between Freud and Einstein (2). The latter wrote to Freud on July 30, 1932, upon the invitation of the League of Nations and its International Institute of Intellectual Co-operation in Paris. His hope was for a "frank exchange of views" on the question that he considered to be "the most insistent of all the problems civilization has to face" and which was simply, "Is there any way of delivering mankind from the menace of war?"

Freud's reply was characteristic. He expostulated against the unscientific nature of the question; he said that he had expected

> a problem on the frontiers of what is knowable today, a problem to which each of us, a physicist and a psychologist, might have our own particular angle of approach. . . . [But] You have taken me by surprise . . . for the question such as it is can only have one possible answer. It is a general principle [he stated, thereby dealing a death blow to the League of Nations and many a failing mind since then] that conflicts of interest between men are settled by the use of violence. (2, pp. 203–204)

The discouraging view of aggression that Freud cast upon psychological thought is still less pessimistic than that of Lorenz and other ethologists. Gorney (3), in a sensitive paper, compared the theories put forward by Freud and Lorenz and stated that the former

"allowed for the possibility that if one could shut off aggression (and violence) at the source, love would still exist." The latter forced the logic to its most bitter conclusion and "carried the instinctual conception of aggression a dismal step further toward hopelessness. Because love was to him [Lorenz] nothing but made-over aggression, elimination of aggression would also eradicate love" (p. 437).

The subtle and dangerous appeal of these theories, which allow man to justify his violence, his lust for power, and his crimes and prejudices, has created a richly divergent atmosphere for discussion. A number of studies now provide convincing evidence that aggression is in fact a learned defensive behavior against threats. In *The Anatomy of Human Destructiveness* (4) Fromm reviewed the evidence against the instinctivist thesis and reached the conclusion that data from the neurosciences, animal behavior studies, and the fields of paleontology and anthropology indicate that the instinctivistic interpretation of human destructiveness is not tenable. Fromm stated that

> while we find in all cultures that men defend themselves against vital threats by fighting (or by fleeing), destructiveness and cruelty are minimal in so many societies that these great differences could not be explained if we were dealing with an "innate" passion. Furthermore, the fact that the least civilized societies like the hunter-gatherers and early agriculturalists show less destructiveness than the more developed ones, speaks against the idea that destructiveness is part of human "nature." (4, pp. 204–205)

Eron and associates (5) have determined, through a 10-year longitudinal study on the relationship between learning conditions in early childhood and aggressive behavior among adolescents, that such behavior is "shaped by learning through socialization practices and varies by sex." They further stated that their findings detract from "the theories of the ethologists who argue that aggression in man is innately determined."

In reviewing the literature one soon becomes aware that when different investigators and authors use the term "aggression," they are not speaking about the same phenomenon. In fact, all of the theories suffer from lack of a clear definition of "aggression" and its distinction from "anger." Furthermore, even though the role of fear and anxiety in this complex of behavior and feelings is acknowledged, the nature of this interrelationship is by no means defined.

Anxiety and Fear

The feeling of anxiety is a familiar one. We experience anxiety under varied circumstances and conditions. At times we are able to locate the source of our anxiety, while at other times we find it very difficult to do so. Fear is an experience similar to that of anxiety. However, in the psychiatric literature a distinction is made between fear and anxiety. Whereas the former seizes upon us simultaneously with an apprehension of known danger and is a direct result of our knowledge of its source, the latter occurs with less clearly conceived synchronization and in the absence of the focus of the danger's source. In an analysis of this distinction Lief (6) wrote,

> Anxiety is a diffuse, highly unpleasant, often vague feeling of apprehension, accompanied by one or more bodily sensations that characteristically recur for the same person. . . . [It] is an alerting signal; it warns of impending danger and enables the person to take measures to deal with a threat. Fear, a similar alerting signal, is ordinarily differentiated from anxiety on the basis of whether the threat is known or unknown, external or internal, immediate or future, definite or vague, nonconflictual or conflictual in origin. (p. 857)

The realities that underlie these distinctions have become part of the popular psychological mythology of our century. The stresses of modern urban life, the pace of industrialization and rapid change, and the increasingly alienated and declining position of the individual in this complexity all combine in the shape of threats, responsibilities, and actual dangers that engulf him; they have all been mentioned at one time or another as causes of the anxiety of modern man. This view is similar to psychoanalytic thought, which postulates that anxiety is a reflection of the existence or anticipation of danger within the human being, which can severely paralyze his proper functioning, lead him to the point of inactivity, and reduce him to a state of near helplessness.

On the other hand, however, some degree of anxiety is essential for the individual's safety and growth. Without anxiety there is little motivation for protecting oneself or improving one's condition in life. At this point we reach the final link in psychiatric thought between anger and anxiety. Rothenberg (7), in his studies on this subject, arrived at the conclusion that anxiety and anger are closely related, since both are the organism's response to threat and danger. He stated

> On the basis of all that is currently known about anger and anxiety, both clinically and experimentally, it seems likely that both of these phenomena are aspects of a diffuse alerted and aroused state. Anger becomes the predominant manifestation of this state when the motoric arousal begins to be directed at the source of threat or obstruction or at an imagined source. Anxiety is the predominant manifestation when the motoric arousal is undirected or is directed toward avoidance or escape. (p. 458)

While these observations are all insightful, they are nevertheless subject to the same dilemma and often seem to be diffuse and directed toward an avoidance of the definition of anger. Rothenberg's most definitive statements, that "anger . . . is always accompanied by anxiety" and that "neither of these manifestations ever seems to occur exclusive of the other" (p. 458) seems at best to invite the mind to further exploration of the relationship between the two. We have yet to arbitrate between normal and abnormal anxiety and to assess the role of anxiety in defending the organism. We need to clarify the relationship among anxiety,

fear, and aggression and to understand the position that anger holds in this equation.

UNDERSTANDING THE PATTERN OF ANGER

The overall pattern with which one must begin the close analysis of anger resides in the primary assumption that life, characteristically and continuously, exposes the individual to threats and opportunities.

Threats can be either actual or assumed. They can originate from the external environment and assume the form of physical or social threat, or they can rise like mist from within and take on the shape of psychological or spiritual crisis. The individual can meet these dangers head-on and with full consciousness, or they can creep up on him gradually and in a disguised form. Some perceive these threats in a realistic manner and respond to them accordingly. The alternative is either to underestimate the intensity of the danger and subject oneself to injuries and afflictions, or to go overboard and respond to the slightest challenge as though it were, indeed, a fearful and destructive danger. Our perception of the danger situation is closely related to our upbringing and our endowments. Once the threat is felt, two major defensive mechanisms are put into motion. They are immediate and automatic—they are innate defensive mechanisms. However, depending on the nature of the individual's life experiences and endowments, one or the other takes a more predominant position.

These defensive mechanisms are fear and anger. A close analysis of these twin mechanisms shows that they both consist of three stages, the first two of which are identical in both. The first component is the alert signal, which informs the individual of the presence or possibility of threat. The second is a condition of anxiety that mobilizes one's needed defensive energy. The third, in the case of fear, consists of an urge for escape or withdrawal, and in the case of anger, involves a desire to attack and thereby eliminate the source of threat. The presence of anxiety, in conjunction with fear and anger, has been observed in both research and clinical work, as Gellhorn (8) has attested. According to Gellhorn, "Chronic anxiety . . . is due to the simultaneous activation of the ergotropic and trophotropic systems at a high level of arousal or psychologically speaking to fear and aggression." The use of the term "aggression" in this context is unfortunate, because Gellhorn was speaking of two emotions, fear and anger. Therefore, when the individual is threatened, defensive mechanisms of fear and anger are mobilized, and both are accompanied by anxiety and an urge to escape or fight.

During infancy and early childhood it is difficult to distinguish between the two responses of fear and anger, since the individual responds with both indiscriminately. As he matures, accumulates experience, and learns from models in his life, one or the other of these defensive mechanisms becomes the primary mode of his self-defense. However, this does not automatically exclude the other defensive response, and indeed, throughout life we respond to threats, to a lesser or greater degree, with both fear and anger. Besides, whenever we respond with either fear or anger the other response is also present, although in a less obvious manner.

These two defensive responses are in the realm of emotions. In this phase the individual has not yet committed himself to any action (behavior).

Following this phase comes the phase of solution. Here the individual has two basic choices. The first is the "objective-creative" solution, which consists of a realistic evaluation of the threat and a unique response to it. During this process the individual assesses the intensity and relative significance of a threat and estimates his own capacity to deal with it. Consequently, he comes to a decision either to carry out his urge to escape or to stand in his tracks and attack the source of danger. In either case, within this "objective" framework, both the fear and anger responses are utilized for the purpose of self-preservation, and as such can be construed as constructive acts.

The other impressive characteristic of the objective-creative solution lies in its essential creativity. An individual, by approaching the threat in a state of full consciousness, draws upon all of his resources, the accumulated force of his inherited endowments and the vast reservoir of his particular life experiences. The final result is necessarily unique and explains why human beings are capable of a multitude of reactions to threats and dangers, all of which are healthy although differing widely in expression. The existence of this creative impulse and its role in the development of an individual's life expression was identified by Adler (9), who stressed, "Do not forget the most important fact that not heredity, and not environment are determining factors—both are giving only the frame and influences which are answered by the individual in regard to his styled creative powers."

The second, or "pathological," solution has its roots in the faulty perception of ourselves and our world. Our personalities, turning on the axis of heredity and environment, set into motion a predictable ebb and flow of anger and fear, with the anxiety that accompanies them. If our models and experiences have adopted the mechanism of anger in preference to fear, the pathological solution manifests itself in the form of aggressive behavior. The divergence between anger, which is not an act, and aggression, which is a learned behavior, becomes clear at this point. Whereas anger is an emotional defense that rises to protect the individual's integrity and does not involve a destructive element, aggression is a negative implementation of that defense which is shaped by specific experiences of the individual and is a learned behavior quite distinct from his integrity.

In the case of fear the individual's pathological behavior manifests itself in avoidance techniques or apathy. Avoidance techniques include all such behav-

iors that allow the individual to underestimate his own capacities, overestimate the intensity and extent of the threats, or both. Individuals with such a lifestyle are fearful, uncertain, apologetic, sickly, and shy. They avoid opportunities and live a life of isolation, avoidance, and emptiness.

Apathy is still another pathological solution used by many in the face of threats. Here the individual, for all practical purposes, avoids solution, abandons hope, and denies possessing inherent capacities and qualities that are obvious to the objective observer.

CONCLUSIONS

The formulation presented here has identified three phases in the development of our response to challenges of life—the threat phase, the innate defense response, and the third phase, which consists of the learned behavior used by the individual as a solution to the threats.

The threats are either from within or without and can be actual or assumed. The response to these threats is in the form of fear and anger, with one or the other taking prominence. Both of these responses are accompanied by chronic or acute anxiety and the urge for escape or attack. The individual's lifestyle, which is the result of interaction between his innate qualities and his life experiences, determines whether he will attempt to deal with these threats, his fear and/or anger, and the resulting anxiety in an objective and creative manner or in a pathological form.

By attempting this juxtaposition between the objective-creative and the pathological solutions to the forces of anger and fear (which arise from the invariable threats that an individual faces during his lifetime), a number of salient points emerge. Among these are the number and types of threats that produce the variations of anger and fear and the necessary mechanisms to decrease and, if possible, eradicate these threats. Furthermore, by differentiating between emotions and behavior, the innate and life-preserving qualities of normal fear, anger, and anxiety are sharply defined and separated from the pathological, life-threatening, and learned behavior of violence and apathy.

Finally, this formulation underscores the need for learning methods of coping with anger and fear from early childhood, so that they do not turn into pathological behavior patterns. In order to arrive at such objectivity, one must first approach the definition of "anger" with an uncluttered mind. Until then, the pathological solutions are inherent in one's interpretation of the word itself.

Episodic Dyscontrol and Family Dynamics

BY HENRY T. HARBIN, M.D.

The author describes characteristics of patients, primarily adolescents, who suffer from episodic violent behavior and their relations with their families. Typical family patterns include overly close alliances by the adolescent with one or both parents and transmission by parents of inconsistent values regarding aggression. Family therapy is the preferred treatment approach; treatment should be active, should initially focus on ways of handling dyscontrol episodes, and should emphasize that the patient is responsible for his or her actions.

THIS PAPER will discuss clinical conceptions of and treatment techniques for patients and families whose predominant symptom is periodic violent outbursts. The sociological and psychological literature documents the high incidence of violence among family members or between intimates. Goode found that at least 50% of homicides were committed by family members or lovers (1). The finding that one-fifth of all police fatalities occur while the officer is intervening in a family argument also points to the need for increased understanding of intrafamilial violence (1). Another statistic that points out the disturbing amount of violence in the family is the increasing incidence of child abuse: some authors have estimated that there are 500,000 to 2.5 million cases per year (2). In addition, juvenile violence is increasing in frequency every year on a national basis. It has been noted that more individuals who commit the four major violent crimes (homicide, rape, assault, and robbery) fall into the age groups 15–17 and 18–24 than into any other age group (3). Several researchers and reviewers of the literature have pointed out the paucity of systematic research into the family interactions of violent individuals (2, 4). These statistics and findings highlight the need to clarify more fully the familial dynamics that may foster repetitive violent episodes.

This paper will present characteristics of patients with episodic dyscontrol who were seen at the University of Maryland Institute of Psychiatry and Human Behavior. The majority of these patients were adolescents treated with family therapy. In addition to violent outbursts, most of these patients had episodes of suicidal behavior. Most of the identified patients had EEG abnormalities (temporal lobe spikes and 6-14/second spikes), and some showed evidence of soft neurological signs. Some patients took anticonvulsant medication or a tranquilizer. (It should be pointed out that, although most of the patients in this sample had some organic involvement, most patients with problems of violence do not.)

Violent behavior consisted of aggression directed at inanimate objects such as windows or furniture, aggression toward other people, sometimes with intent to kill, dangerous misuse of automobiles, and repetitive violence when drinking alcohol. Suicidal behavior sometimes occurred in conjunction with aggressive outbursts. For example, one patient put his hand through a window in an attempt to cut his wrist while he was angrily breaking up furniture.

A family therapy approach to violent behavior emphasizes the communicational meaning of the assaultive behavior and attempts to change the interactional patterns that maintain this dysfunctional symptom. Organic instability increases the vulnerability of the adolescent or young person to a multiplicity of family and developmental pressures, some of which may be of sufficient magnitude to lead to a dyscontrol episode. However, once the cycle of violence is set in motion, these episodes may take on an adaptive function for the family. The dyscontrol episodes may serve as the final common pathway for other family members' stresses, may be an attention-seeking mechanism for an individual, or may serve a protective function by shifting the focus away from covert marital problems. It is important to evaluate and weigh the overall mixture of intrapsychic, interpersonal, and organic variables that influence dyscontrol episodes before deciding on a particular treatment approach.

TYPICAL FAMILY PATTERNS

Overly Close Alliances

In reviewing cases treated in our hospital as well as families that were only evaluated, I noticed certain repetitive family interaction patterns. A violent adolescent or young adult frequently has a close, almost symbiotic, emotional bonding with one parent; the other parent is usually only indirectly or ineffectually involved. Covert and overt marital disturbances are almost always present with this constellation. Of course, one of the major developmental tasks for the symptomatic young person is separation from the family and increasing autonomy from parents. The parents them-

Dr. Harbin is Assistant Professor, Institute of Psychiatry and Human Behavior, Department of Psychiatry, University of Maryland School of Medicine, 645 W. Redwood St., Baltimore, Md. 21201.

selves are usually struggling with middle-age life crises, declining health, and identity confusion; these issues are intertwined with the difficulties of the adolescent. The natural ambivalence of the young person while separating will be exaggerated due to the overly close relationship with one parent and will swing from intense hostility to equally intense guilt and shame. The adolescent's attempts at separation invariably cause stress for the parents and siblings as their dependency on the adolescent is disrupted.

The following case example shows the symbiotic relationship between a violent male adolescent and his mother. Therapy with this family continued over a period of 6 months; at the end of this time the therapeutic goals of cessation of violent outbursts, increased autonomy for the adolescent, and reinvolvement of the father with the family had been successfully reached.

A, a 17-year-old male, was referred because of several episodes of violent behavior. His mother and father participated in outpatient therapy. Both parents were frightened and concerned about what was happening with their son. The mother was the dominant figure in the sessions, and her questions and actions relating to her son were very intrusive. The father was somewhat passive and distant and seemed too timid to intervene in child-rearing matters, thereby abdicating his role. A was particularly confused about his life goals and would swing from wanting to live at home to wanting to elope with his girl friend. His first violent outburst occurred while he was with his girl friend and was fantasizing about how much money he owed his mother and how he would never be able to pay off his debts to her. He became extremely anxious and began to smash chairs, threatened to hit his girl friend, and finally broke a window with his hands. It required several people to control A, and he was hospitalized. He had only a sketchy memory and awareness of the events during his rage reaction.

It was subsequently determined that A had 6-14/second EEG spikes and he was placed on diphenylhydantoin. He was certainly in a situation in which his loyalties were split between his girl friend, who was as domineering as his mother, and his mother, to whom he owed a much greater emotional debt. He seemed to be torn between the alternatives of either destroying himself or someone else as a response to this dilemma.

The following case also shows an overly close relationship between parent and child, but this time both parents are involved.

In this family the symptomatic person was the 19-year-old son, B, who had periodic outbursts of violence followed by suicidal behavior such as head banging and attempts at hanging himself while under the influence of alcohol. B also drove his automobile very recklessly while drinking and had had several accidents. He was involved in a very hostile, dependent relationship with his mother and a more positive but symbiotic relationship with his father. The father was extremely dependent on his son and had great difficulty in setting limits for fear of hurting him or driving him away. The mother, however, was extremely hostile and rejecting at times. The marital relationship was chaotic, and there was a great deal of emotional distance between the spouses. B was unable to separate from home even though he had stated often that this was his only wish. Whenever he became angry with his parents for setting limits or disagreeing with him he would leave the house and get drunk; sometimes he became involved in provocative or assaultive actions with police when they attempted to arrest him or stop him for misusing his car. B had some evidence of brain dysfunction on EEG tracings.

In these examples and others, one sees the adolescent's alternations between extreme hostility toward self and others and extreme (mutual) dependency with the parents. Steirling points out that guilt over leaving a home that is overly close can cause an adolescent to be overcome by self-destructiveness (5). The psychopathology of the parents, the inability of the parents to negotiate their marital problems, the young person's confusion and fear about separating from home, the instability of the young person's central nervous system, and the poor self-esteem of both parents and child all add together to create a milieu in which episodes of behavioral dyscontrol can take place.

Distortions in Value Transmission

Another frequently repeated pattern in these families is inconsistency in the values and limits concerning aggression transmitted by the parents to the adolescent or young adult. The parents may react very angrily to violent behavior at one time and then disqualify this limit by ignoring the same misbehavior another time. One parent may punish a certain behavior while the other parent subtly encourages it so that the child is caught in a covert conflict between the spouses. Other parents react to extremely violent behavior with a bland affect and seem afraid even to discuss punishments for these difficulties. This inconsistency in limit setting has been described in other families with delinquent adolescents; however, when delinquent behavior is violent, this inability to set limits can be an extremely grave and dangerous problem. The following clinical example demonstrates the problem of parental inconsistency and how it can affect the offspring.

A 17-year-old girl and her family were referred because she had set two fires in an attempt to kill both her family and herself. During the first interview the parents seemed unable to hold their daughter accountable for her extremely destructive behavior. They seemed fearful of confronting her, as if they could not bring themselves to face the fact that their daughter had tried to murder them. Even when the therapist attempted to interject some of the missing affect and dangerousness of the situation, the mother responded that perhaps they should forget about the past and try to start over again. The 15-year-old brother of this adolescent girl also had frequent violent "accidents"; once he had cut his younger sister's lip. Even when he slugged his sister in the stomach at a family party and knocked her down, the parents did not see the need to punish him. This lack of parental follow-through of punishment was mixed with frequent verbal diatribes about the evils of disrespect and hostility. This inconsistency between words and behavior made it difficult for the children in this family to know where the limits were for their own drives, particularly their aggressive urges.

Many parents of children who are violent seem almost immobilized by guilt over their own seeming failure as parents. They feel that they are at fault for not having prevented the symptom through better parenting in the past. They feel that they have no right to be the authority in the present because of their past failures. The adolescent or young adult may exploit this shame by accusing the parents of past lapses in proper limit setting. The therapist may also unwittingly exacerbate this guilt by asking questions about the past and either clarifying or bringing into awareness mistakes that the parents made.

Another element that contributes to inconsistency in the transmission of values is the parents' fear of the young person's violence. This fearful reaction and consequent withdrawal by the parents from confronting the symptomatic behavior is most evident in one-parent families. The following examples show how this fear affected two patients whose fathers were not in the home and who lived with their mothers.

A rather large, heavyset 27-year-old man was living with his mother and two sisters. He had had several episodes of intrafamilial violence while under the influence of alcohol. He had hit and kicked both his mother and sisters over a 2- to 3-year period. The family sessions revealed that they had never even confronted this man with his behavior, largely because of their fear of him. In fact, the patient had not known about the extent of his violent actions because he had been drunk and his family had never told him. He responded with a great deal of shame to this confrontation and renewed his efforts to control his drinking.

A 19-year-old boy had repeatedly attacked his mother and sisters in the home. Twice the mother had to go to the hospital for treatment of injuries inflicted by the patient. However, she had never sought outside help in controlling her violent son. In fact, during one incident the patient himself called the police to come arrest him.

PSYCHOTHERAPEUTIC CONSIDERATIONS

Before deciding on a treatment approach, it is necessary for the therapist to thoroughly evaluate the extent and nature of the violent actions and the degree of dangerousness, as well as to consider the necessity of a neurological workup. It is important to evaluate the family dynamics as well as the individual's problems. In my experience, a family therapeutic approach provides much more leverage than individual therapy because it makes the patient's most important interpersonal environment accessible to the therapist. Family therapy is particularly indicated when the aggressive act is directed toward another family member, unless, of course, the violent actions are of such magnitude that the person must be hospitalized or jailed.

In general, the therapist must be active and directive in attempts to change the violent symptoms. Haley (6) and Minuchin (7) have described detailed strategies for actively changing behavioral symptoms via a shift in the family structure. One of the most immediate and primary interventions that a therapist should make with these families is to clarify and systematize the steps to be taken if another violent episode occurs. This therapeutic action will accomplish several goals: 1) it will decrease the parents' or other family members' fear because they will have a more clear and definite plan of action; 2) it will push the parents to confront a young person or adolescent who is acting out aggressive urges, thereby encouraging more open communication between them; 3) it will push the parents to be more consistent and specific in their limits with the adolescent, thereby leading to a clarification of the usually blurred generational boundaries; and 4) it will decrease the symptomatic person's fears of losing control by showing him that he can be managed by others in the immediate environment.

The parents need to be told that they should call the police, if necessary, and that the young person can be taken to an emergency room or even to a correctional institution if he or she is completely out of control. Certain available members of the extended family or neighbors may be identified as persons who can be called upon to intervene in an emergency. The parents need the support of the therapist as an authority in order to help them reestablish their own authority over their offspring.

These actions by the therapist should be carried out during the first one or two sessions, particularly if the violence is life threatening. If a dyscontrol episode occurs during therapy the family's handling of the matter should be examined in great detail, and any inconsistency or confusion should be remedied. After clarification of behavioral limits has been accomplished, the therapist can work on other underlying problems in the family, such as overly close alliances between parents and children, marital dysfunctions, or covert depression and suicidal thoughts in family members. It is important to keep in mind that whenever a sensitive problem for the family is being worked through, the potential for violence from the identified patient will increase.

When the symptomatic adolescent is diagnosed as having a seizure disorder and is placed on medication, family psychotherapy becomes more complicated. The diagnosis may intensify an already-existing belief on the part of the parents that the adolescent is not accountable for violent behavior because he is physically "ill" and, therefore, not responsible for anything that happens. This may make it even harder for the young person to disentangle himself from the family. The therapist can help by pointing out that seizures of any kind are triggered by emotional conflicts and stress and that everyone in the family can work on coping with this stress in ways that will decrease the likelihood of a violent episode. A further explanation is also necessary; the adolescent or young adult must be told that he is responsible for whatever physical or personal damage is done during a dyscontrol episode, regardless of whether there is a partial organic etiol-

ogy. These dynamics were evident in the case of A, mentioned above.

During family therapy A had several more dyscontrol episodes. In one of these the parents called the police and neighbors to control their son and had him taken to the emergency room. The father then cleaned up the mess and repaired the broken furniture for his son. The therapist asked the parents not to do this in the future and had them clarify with the son that he was responsible for his behavior. At first A became angry and said that he had a medical problem and could not be responsible for his behavior. The therapist replied that it was true that he had a medical problem but that there was no one else to hold responsible for his behavior but himself and that this is what would happen. The next weekend A had one more violent episode, but this time he had to repair all the furniture and pay for the damage out of his own pocket. He did not like this, but he did not have any further dyscontrol episodes.

Another common problem in treating these families is the emotional reaction of the therapist. Violent individuals can stir up fear or intense anger in the therapist that can lead to countertherapeutic actions. Lion and Pasternak (8) described in some detail the countertransference reactions involved in treating violent patients in individual therapy. One of the greatest dangers for the family therapist is that his emotional reactions are likely to be the same as those of the family members; this may lead to an intensification of conflict on both sides. The family therapist is not only reacting emotionally to the identified violent patient but also to the anxiety or denial of anxiety of the other family members. The therapist may withdraw and become paralyzed by fear that he is going to be attacked, just as some parents do, and thus be unable to effect positive action. He may react by scapegoating the symptomatic member and ignoring family pathology, thereby further isolating the violent person. It is important to have colleagues to consult with when treating these families in order to maintain a sense of objectivity and neutrality, which can be easily lost in the face of such disturbing behavior.

Plasma Testosterone in Homosexual and Heterosexual Women

BY NANETTE K. GARTRELL, M.D., D. LYNN LORIAUX, M.D., PH.D., AND THOMAS N. CHASE, M.D.

The authors measured plasma testosterone levels in 21 homosexual women and 19 age-matched heterosexual women. Although values for the two groups overlapped considerably, testosterone concentrations averaged 38% higher in homosexual than in heterosexual subjects. A statistically significant inverse correlation between age and testosterone level was found for heterosexual but not for homosexual women.

THE DEVELOPMENT of improved techniques to measure hormone levels in plasma has stimulated a broad reevaluation of the possible endocrinologic basis of human sexual function. For example, recent studies have shown that plasma testosterone concentrations in men correlate with sexual activity, although mean circulating levels of the hormone in practicing homosexual and heterosexual men are no different (1–7). The possible influence of testosterone on female sexual behavior has yet to receive as much investigative attention; however, previous observations of urinary excretion patterns suggest that testosterone concentrations in homosexual women may exceed those in heterosexual women (8–10). In this study, we report that plasma testosterone levels in homosexual women, measured by radioimmunoassay (11), appear substantially higher than those of heterosexual women of the same age.

Dr. Gartrell is Clinical Fellow in Psychiatry, Harvard Medical School, and psychiatric resident, Massachusetts Mental Health Center, Boston, Mass., Dr. Loriaux is Chief, Developmental Endocrinology Section, Reproduction Research Branch, National Institute of Child Health and Human Development, Bethesda, Md., and Dr. Chase is Director, Intramural Research, Experimental Therapeutics Branch, National Institute of Neurological and Communicative Disorders and Stroke, 9000 Rockville Pike, Bethesda, Md. 20014. Address reprint requests to Dr. Chase.

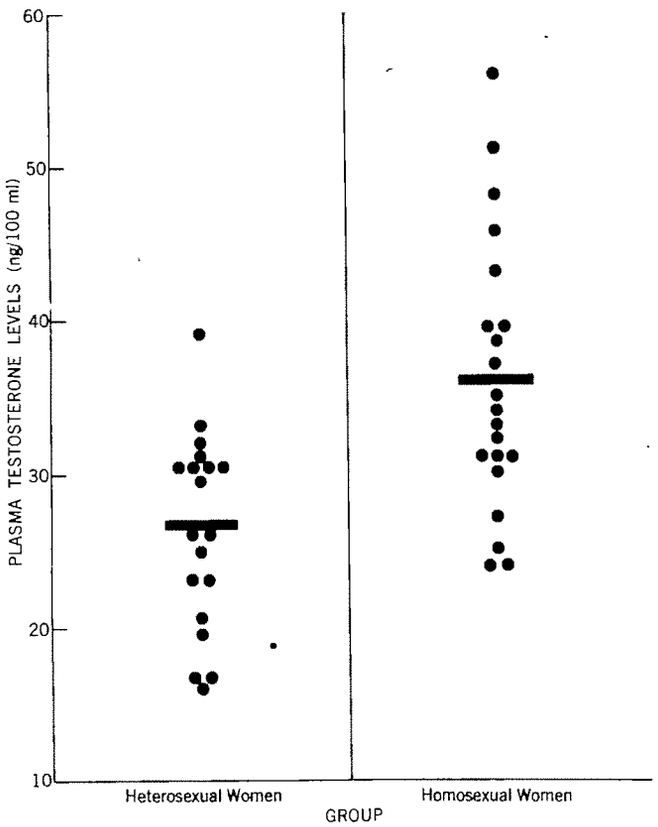
METHOD

Twenty-one homosexual women (referred by local homophile organizations) were age matched with 19 heterosexual women; all had volunteered to participate in this study after full discussion of its purposes, procedures, and potential risks. The age range of the homosexual women was 21–35 years (mean=26.8±0.80) and that of the heterosexual women was 21–33 years (mean=26.0±0.74). Sexual practices of study subjects during the preceding year involved only individuals of the same sex (for homosexuals) or opposite sex (for heterosexuals). None of the individuals studied were taking birth control pills or other steroid preparations or using marijuana frequently. All were found to be in good general health, nulliparous, and free of menstrual irregularities, hirsutism, or abnormalities of the external genitalia. Each underwent venipuncture at 8 a.m. on the first, second, and third days of her menstrual period. Day one was defined as commencing on that 8 a.m. which occurred within 24 hours of menstrual onset. Plasma separated from the resulting samples was stored at 0°C until testosterone assays were carried out. Plasma testosterone was measured by a modification of the method of Nieschlag and associates (11) with LH-20 Sephadex as the chromatographic medium (12). Reported testosterone values are average levels for the three-day specimens, corrected for percent recovery, which ranged from 60% to 90%.

RESULTS

As shown in figure 1, testosterone values for the heterosexual women ranged from 16–39 ng/100 ml (mean=26±7 ng/100 ml), and values for the homosexual women ranged from 24–56 ng/100 ml (mean=36±11 ng/100 ml). Thus, although ranges for

FIGURE 1
Plasma Testosterone Levels in Homosexual and Heterosexual Women



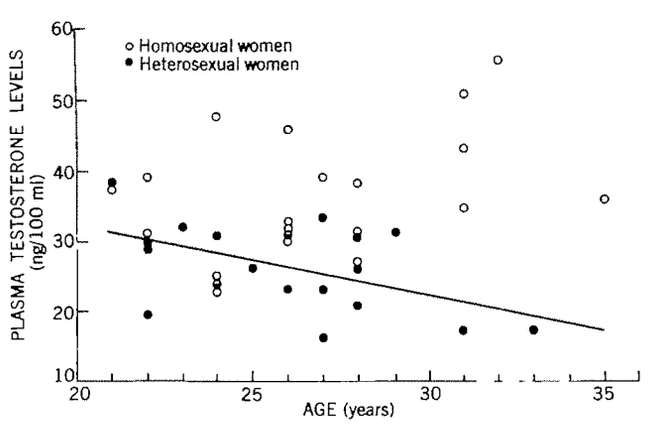


FIGURE 2
Plasma Testosterone and Age in Homosexual and Heterosexual Women

the two groups overlapped considerably, circulating testosterone values in homosexual subjects averaged 38% higher than those in the heterosexual group ($p<.001$).

It is unlikely that the observed differences in testosterone levels reflect age differences between the two groups studied, since the mean age of the homosexual women did not differ statistically from that of the heterosexual women. Moreover, in the heterosexual group, a statistically significant inverse correlation ($r=-.518$; $p<.02$) existed between age and testosterone concentration (figure 2). In the homosexual group, a slight tendency in the opposite direction was observed ($r=.359$; $p>.05$).

DISCUSSION

Results of this investigation support and extend earlier conclusions derived from analyses of testosterone in urine (8–10), even though such excretion studies are complicated by the collection of samples without regard to phase of menstrual cycle (8, 13, 14), by the low urinary levels of unmetabolized testosterone, as well as by the absence of any unique testosterone metabolite (15–17).

Available information precludes drawing any behavioral conclusions about the apparent association of elevated plasma testosterone levels and female homosexuality. Such factors as sleep, stress (5), mood or lifestyle might, for example, affect circulating levels of this hormone. Moreover, there is currently no basis for speculating whether the observed endocrinologic differences might reflect a primary mechanism for or a secondary response to a particular sexual orientation.

A Study of 100 Physician Psychiatric Inpatients

BY ROBERT ERWIN JONES, M.D.

The author reviewed the case records of 100 physician inpatients in a private psychiatric hospital. He found that these physicians were more likely to have diagnoses of affective disorder and drug abuse than the general psychiatric hospital population, that their peak susceptibility occurred in their late 40s, that general practitioners and psychiatrists were overrepresented, and that female physicians were almost four times more vulnerable to suicide than male physicians. He describes some critical aspects of engaging the disabled physician in psychiatric hospitalization.

ALTHOUGH THE EMOTIONAL MORBIDITY of physicians is becoming better documented (1–8), there are still surprisingly few studies of psychiatric illness among physicians, except in the area of drug addiction. Reports on physician psychiatric inpatients consist of those by Pearson and Strecker (9), who studied 20 physician inpatients at the Institute of Pennsylvania Hospital; Duffy and Litin (10), who studied 93 at the Mayo Clinic; A'Brook and associates (11), who studied 114 at two English hospitals; Simon and Lumry (12), who studied 36 at the Minneapolis Veterans Administration Hospital; and Pond (7), who studied 29 physician inpatients at the Priory Hospital and 23 physician inpatients and outpatients at the Maudsley Hospital.

To augment this small but growing body of literature about psychiatric illness among physician inpatients, in this paper I will review data from the hospital case records of 100 physicians admitted to the Institute of Pennsylvania Hospital, a private psychiatric hospital, from 1967 to 1975. I will take special note of diagnosis, precipitating factors, alcohol and drug abuse, suicide, admissions of female physicians, and leaving against medical advice.

The 100 physician inpatients in this study were distributed in age at first admission as follows: in the 10–19-year-old group there was 1; 20–29, 5; 30–39, 22; 40–49, 38; 50–59, 23; and 60–69, 10; 1 of the patients was 89 years old. The average age was 45. The age distribution indicates a peak in the 40s. One interesting patient was first treated in this hospital at age 13 for more than a year for an illness described as catatonic schizophrenia. After he completed medical training, he returned three times to the hospital for treatment of manic-depressive illness with lithium carbonate; meanwhile, he has continued to work in medical research.

The 100 inpatients had a total of 200 admissions; 59 of these were single admissions. There were 5 1-day admissions. One nearly 5-year admission was that of a senile physician who died. Fourteen patients had 2 or 3 admissions in 1 year, indicating a cluster of admissions for one illness and possibly indicating that the first admission should have been longer. Eleven patients had 5 to 10 admissions to other hospitals. The average length of stay for the 100 inpatients was 36.5 days. The average length of stay for the drug- and/or alcohol-abusing patients was 29 days. Hospital stays of addicted physicians were only 10 days or less in 16 cases, indicating that detoxification rather than psychotherapy was the goal.

DIAGNOSIS

Table 1 indicates the primary diagnoses of the 100 physicians admitted in 1967–1975. The table also shows the diagnoses of 9,567 patients discharged from the hospital in the same period (13).

In the physician inpatient group, affective disorders

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Jones is Clinical Professor of Psychiatry, Jefferson Medical College, Thomas Jefferson University, Philadelphia, Pa. 19107.

*According to the U.S. Department of Health, Education, and Welfare (14).

(depressive neurosis, manic-depressive illness, psychotic depressive reaction, involutional melancholia, and depressive adjustment reaction of late life) accounted for 68% of all conditions. A greater proportion of the physician inpatients had a depressive diagnosis than the hospital population as a whole. Simon and Lumry (12) found that depression was the complaint of 86% of the 36 physicians they studied and that 41% of their group were preoccupied with suicidal ideas.

The percentage of the 100 physician inpatients in our hospital in 1967–1975 who were drug addicted and/or alcoholic was about triple the percentage in the total hospital population over the same period, but schizophrenia was diagnosed much less frequently in these physicians.

The accuracy of psychiatric diagnosis of physicians is open to question because psychiatrists have a propensity to protect their medical colleagues from such potentially damaging labels as alcoholic, drug addict, and schizophrenic. Especially in the area of drug and alcohol abuse the statistics may be inaccurate. For example, for the 100 physician inpatients in our hospital, alcoholism was the primary diagnosis in 5 cases and the secondary diagnosis in 7; however, the case histories revealed noteworthy alcohol abuse in 12 additional cases. Drug addiction was the primary diagnosis in 7 cases and the secondary diagnosis in 6; however, drug abuse was recorded in an additional 9 case histories. Combined alcohol and drug abuse was described in 6 more case histories that did not carry the diagnosis of either type of dependency. Thus, although only 12 of 100 patients carried the primary diagnosis of alcohol and/or drug abuse, according to the case records more than half (N=52) actually had a substantial drug and/or alcohol problem.

The most common diagnosis used in undiagnosed alcohol and/or drug abuse is depressive neurosis; this fact helps to explain the high proportion of affective disorders in this series of physician inpatients. The reasons for such concealment of the facts are related to insurance benefits, lack of knowledge about diagnosis and treatment, and countertransference factors such as overprotection of the patient.

A comparison by specialty of these hospitalized physicians with the medical population of the United States indicates that general practitioners and psychiatrists were overrepresented but surgical specialists were underrepresented among these hospitalized physicians (see table 2). I can only speculate on the reasons for this disparity. The premorbid personality types of the different specialists is probably important. Also, general practitioners and psychiatrists tend to practice alone in their offices, but surgeons practice as members of teams and therefore receive the daily support as well as the scrutiny of their peers.

PRECIPITATING FACTORS

The psychiatrists who recorded the case histories studied were impressed with the compulsive, hard-working nature of the physician inpatients and their

drive for accomplishment and achievement. Some descriptions of the premorbid patients are as follows: "perfectionistic," "achiever," "overworked, then builds up resentment about extra duties," "has a large, successful practice," "driven to be successful," "driving hard," "has grandiose ideas about his practice," "could not refuse to accommodate patients," "complete preoccupation with work." A suicidal pathologist said, "The perfect doctor spends a great deal of time and energy in his role as a physician." The records have repeated references to the patient's inability to relax, such as "no vacation in five years." One general practitioner had not taken a vacation in 15 years! An alcoholic physician whose hospital privileges had been revoked because of his drinking had worked 7 days a week, seeing more than 100 patients daily. One amphetamine user had overworked at two hospitals, putting in 80–90 hours a week. The records give the impression that it was not so much the overload that created a burden for the physician as it was the overzealousness of the physician who attempted to handle the workload. In other words, the personality of the physician may have been more important than the occupational stress.

Although pressure of work was the most commonly given reason for hospitalization by the recording physicians, marital discord was also frequently cited. One record described a physician whose "practice was so busy it interfered with marriage." Interestingly, the records are noticeably inadequate in sexual histories, except for sporadic mention of poor sexual adjustment. This might reflect a reluctance on the part of psychiatrists to question their colleagues about such matters or to record the information. Concern about other family members and financial worries were the next most common reasons for hospitalization reported.

ALCOHOL AND DRUG ABUSE

In the drug- and/or alcohol-abusing group, toxicity and its consequences often precipitated admission. Four physicians had suffered falls and 2 had had automobile accidents after drinking. Eleven physicians had had staff privileges revoked by their peers, and 2 had had their medical licenses revoked. In only one instance was it recorded that a patient had complained that the physician was intoxicated, and there is no mention in these records of malpractrice that might be attributed to mental illness or addiction.

Even if pressured to enter the hospital by colleagues or family, most of these physicians (N=95) were admitted as voluntary patients. Four physician inpatients (2 schizophrenic, 1 manic, and 1 acutely intoxicated) required emergency detention, and 1 senile patient was committed by the court. The reluctance of physicians to seek treatment for either physical or emotional illness has been cited by many authors (9). Seventeen of the 100 physicians in our hospital had sought outpatient therapy before hospitalization.

TABLE 3
Specialties and Age Groups of 16 Suicidal Physician Inpatients

Age groups	
20–29	3
30–39	3
40–49	4
50–59	4
60–69	2

SUICIDE

Fifteen of the 100 physicians attempted suicide before admission, and 1 did so immediately afterward. Four others had attempted suicide on previous occasions. Seventeen more described suicidal thoughts that prompted their admission. Fourteen of the 16 suicide attempts were by overdose, 1 by shooting in the chest, and 1 by laceration of the neck. Thirteen of the 16 entered the hospital with a diagnosis of depression. Seven of the 16 had a history of drug or alcohol abuse. The specialties and age groups of the suicidal patients are shown in table 3.

In light of the fact that 37% of the hospitalized physicians had a history of suicidal thoughts or attempts, the prevention of suicide must be uppermost in the minds of the treating physicians. Two physician inpatients in this series made serious suicide attempts after admission to the hospital. Strenuous efforts at prevention of suicide must continue after a patient enters the hospital.

It is interesting to note that none of the 15 patients who made suicide attempts just before admission was treated with ECT (although 3 others in the total group received ECT). I do not have follow-up information about this suicidal group. The rate of unsuccessful suicide attempts in this series (16%) is comparable to the reported suicide rate among physician psychiatric patients (5%–19%) (4).

FEMALE PHYSICIANS

All of the 11 female physicians in this study group entered the hospital voluntarily. Eight of them admitted themselves for treatment of depression (5 neurotic, 2 manic-depressive, and 1 depressive adjustment reaction of late life). Six were general practitioners. Five had attempted suicide by means of overdose before admission, and 1 of these again attempted suicide by

laceration after admission. Four of the 5 who attempted suicide were Roman Catholic, and 3 were unmarried. This high percentage of suicide attempts (45%) contrasts markedly with the lower percentage among male physician admissions (11 of 89, or 12%). The average age of the suicidal women was 40, while that of the men was 49, indicating that younger unmarried female physicians are vulnerable to suicide, while the peak period of vulnerability for men is middle age.

DISCHARGE AGAINST MEDICAL ADVICE

Nine physician inpatients left the hospital against medical advice; 8 of these were drug and/or alcohol abusers. This rate is substantially higher than the overall rate of such discharges from our hospital, which was 1.1% over the 2-year period 1971–1973 (15).

COMMENTS ON TECHNIQUES OF CARE

The responsibility of caring for emotionally ill physicians rests with physicians. This unusual situation arouses denial, avoidance, resistance, hostility, and other defenses in both patient and doctor. Moreover, the family of the physician very often does not know how to care for the sick physician and turns to his or her colleagues for assistance. These, of course, are the very people from whom the potential patient may wish to hide the illness. The moment when the sick physician's family seeks expertise is critical because his or her colleagues' attitude and conduct can greatly influence future events for the patient, especially the patient's own attitude toward his or her illness. The colleague must be careful not to minimize the condition, not to avoid the situation, not to retreat and do nothing, but to respond with constructive guidance and compassion.

More effective and supportive mechanisms can be developed to care for sick hospital staff members, such as the Committee on Staff Health of the Institute of the Pennsylvania Hospital, a group of experts who offer confidential, nondisciplinary help. Physicians or their families may consult this group about a staff member's disturbed behavior. The group recommends proper care while safeguarding the potential patient's staff position, thus preventing rejection or humiliation by fellow staff members.

Physicians should not be afraid to use peer pressure. On the basis of our records, I would say that peer leverage—discontinuance of admitting and operating privileges, for example—is an effective and safe mechanism for prompting the hospital admission of the disturbed physician. The timely and compassionate use of this mechanism is much better than legally revoking a license later. A critical moment comes after the medical staff has decided to compel a colleague to obtain treatment. The staff must keep in mind that even if he or she denies it, which is likely, the potential patient is most likely depressed (there is at least a 60% chance), is very likely abusing alcohol or drugs (a more than 50% chance), may very likely have marital or family difficulties, and, faced with loss of income during hospitalization as well as with loss of prestige because of losing staff privileges, may develop suicidal thoughts (a more than 30% chance) or make a suicide attempt (a 15% chance). After the medical staff has decided to recommend hospitalization, it is essential that they exercise maximum care of the patient until he or she is safely in professional hands.

Engaging any alcoholic patient in treatment requires special technique; the alcoholic physician is no exception. One technique that is sometimes of value is direct confrontation of the patient by concerned members of the family. These family members must be carefully prepared ahead of time about the method and goals of the confrontation. Follow-up care is of utmost importance. A medical Alcoholics Anonymous may be available. The initial phase of hospital care is fraught with danger. Therefore, I would not hesitate to assign private duty nurses to physician inpatients for the first days of hospitalization until treatment is well under way.

I do not have accurate reports of follow-up care or results, but other authors have commented on the reluctance of physicians to remain in outpatient care. In my experience, the physician who seeks hospital care in a crisis quickly reasserts his or her driving, overachieving mechanisms and is not motivated to explore his or her personality, often giving lack of time and the pressures of medical practice as the reasons. Patients with chronic or recurrent illness require special consideration and are well advised to work in structured supervised settings where others can monitor their condition. Physicians who have multiple psychiatric hospitalizations need not fear that they cannot continue to practice medicine. Our records show that some physicians with repeated hospitalizations have maintained successful careers.

One way in which the psychiatrist might err in treating physicians is in assuming that all physicians are knowledgeable about psychiatry or psychotherapy. It is important to be instructive about psychiatric terminology, the goals of treatment, the mechanisms of drug actions, and the process of psychotherapy, just as with any other, nonmedical patient.

On the Safety of Long-Term Treatment with Lithium

BY MATTHEW J. FRIEDMAN, M.D., PH.D., CHARLES M. CULVER, M.D., PH.D., AND RICHARD B. FERRELL, M.D.

Thirteen patients with bipolar affective illness who had received lithium therapy for 1–5 years were tested retrospectively for evidence of cortical dysfunction. Data on patients younger than 55 show no abnormalities on the Halstead-Reitan Neuropsychological Battery and suggest that chronic lithium therapy is relatively safe. Significantly elevated Halstead Impairment indexes were observed among elderly patients, but these data are difficult to interpret.

IT IS WELL known that lithium toxicity can result in a variety of central nervous system (CNS) abnormalities. Schou and coworkers (1) originally described 5 toxic patients exhibiting confusion, convulsions, or coma who made full recoveries within 6 weeks. Other investigators have also reported full recovery from lithium toxicity after discontinuation of the drug (2–4). A few reports have challenged the assumption that a patient who recovers from lithium intoxication will be free from persistent neurological sequelae. Von Hartitzsch and associates (5) described 2 patients in whom prolonged lithium intoxication was followed by permanent damage to basal ganglia and cerebellum. Permanent brain damage has likewise been reported by Juul-Jensen and Schou (6), although the contribution of diphenylhydantoin must be considered in 1 case, and by Cohen and Cohen (7) in 4 patients treated with lithium and haloperidol concurrently.

Much more disturbing are reports of adverse reactions among patients receiving therapeutic levels of lithium carbonate. Confusion, convulsions, dysarthria, cogwheel rigidity, and coma (8–13) have been observed in patients whose serum lithium levels did not exceed 1.5 mEq/liter. Alterations in EEG, consisting of diffuse high-voltage slow waves that disappear after discontinuation of medication, have also been reported at therapeutic levels (14–16). There are also a few reports of persistent focal EEG changes (16–18). Finally, Small and coworkers (19) have demonstrated significant neuropsychological impairment among patients maintained on therapeutic doses of lithium for only 3 weeks.

We became interested in this problem after observing 2 manic-depressive patients who developed persistent cortical dysfunction following acute lithium intoxication. We wondered whether manic-depressive patients maintained on chronic lithium prophylaxis for several years would exhibit any evidence of cortical dysfunction. Therefore we interviewed 13 patients with bipolar affective illness who had not experienced lithium intoxication and assessed cortical dysfunction by both EEG and the Halstead-Reitan battery.

METHOD

The 13 subjects were patients at the Dartmouth-Hitchcock Mental Health Center, Hanover, N.H. All

Dr. Friedman is Assistant Professor of Psychiatry and Pharmacology, Dartmouth Medical School, Hanover, N.H., and Staff Psychiatrist, Veterans Administration Hospital, White River Junction, Vt. 05001. Dr. Culver is Associate Professor of Psychiatry and Dr. Ferrel is Assistant Professor of Psychiatry, Dartmouth Medical School.

This work was supported in part by a research starter grant from the Pharmaceutical Manufacturers Association.

had manic-depressive illness and had been included in a previous investigation on manic-depressive illness in families (20). Criteria for the diagnosis of bipolar affective illness included a history of at least one episode of illness lasting 3 or more weeks in which two of the three following manic signs or symptoms were evident: elated mood, flight of ideas, and hyperactivity. In addition, at least four of the following were required: decreased need for sleep, grandiosity, intense irritability, excessive plans, distractibility, increased sexual drive, pressure of speech, or extravagance. Individuals with a history of alcoholism or thought disorder were excluded. Thirteen of the original 39 patients studied by Goetzl and associates (20) had remained on lithium carbonate therapy and agreed to participate in the present study.

The CNS status of each patient was assessed by EEG and by Reitan's modification and elaboration of the Halstead neuropsychological test battery (21). The Halstead-Reitan battery is a sensitive indicator of the integrity of the cerebral hemispheres (22). It consists of the Wechsler Adult Intelligence Scale (WAIS), the Trails Test, the dynamometer, the Category Test, the Tactual Performance Test, finger tapping, the Speech Sounds Perception Test, the Seashore Rhythm Test, and a sensory and an aphasia examination. The impairment index represents a general approximation of the degree of cognitive deficit. According to Reitan, an impairment index of 0.5 or less is generally within normal limits. We also interviewed each patient and reviewed medical records to obtain data regarding lithium dosage, duration of therapy, serum lithium levels, use of other medications, and the patient's view of his or her illness before and after lithium maintenance therapy was initiated. It should be noted that before lithium therapy was initiated all patients had received a thorough neurological examination; no neurological abnormalities were detected in any patient at that time.

RESULTS

All patients were clinically euthymic at the time of this assessment and all were receiving lithium carbonate in maintenance doses of 600–1500 mg/day. The duration of maintenance therapy ranged from 1.2 to 5 years, with a mean of 3.2 years.

Every patient reported that lithium had changed his or her life. Before beginning lithium therapy each patient had been hospitalized at least once. Subsequent to treatment 9 patients reported no further hospitalizations, 3 reported one relapse, and 1 patient had required hospitalization twice. Table 1 shows individual patient data related to duration of illness, duration of lithium therapy, daily dose, and serum lithium level at the time the testing was conducted.

Twelve of the 13 patients had normal EEGs. The single exception, patient 3, was a 25-year-old woman who had received lithium carbonate for 3 years and whose serum lithium levels had remained within the therapeutic range. Her EEG was symmetrical with paroxysmal variations in voltage and rate throughout the record, which was interpreted as "an abnormal record suggestive of a seizure disorder." Neurological findings were within normal limits and there was no history of seizures or symptoms suggestive of a seizure disorder.

Among the 8 younger patients (aged 18–53) given the full Halstead-Reitan battery of neuropsychological tests (patients 1–8 in table 1), 7 showed no evidence of cognitive impairment or cortical dysfunction. All had impairment indexes of 0.1–0.3 and in none of their test results was there evidence of even mild focal cortical dysfunction or mild delirium. One patient had a testing record that was questionably borderline abnormal (patient 6 in table 1). He was a 41-year-old high school graduate with a WAIS full-scale IQ of 100 and an impairment index of 0.6. There was no evidence of focal cortical dysfunction but four of his seven Halstead battery indexes were in the lower end of the impaired range (Category Test, 72 errors; Tactual Performance Test, total time=18 minutes, 39 seconds; Tactual Performance Test (location), 2 correct; and Seashore Rhythm Test, 27 correct). We would judge his test results to be essentially normal or to indicate at most a very mild diffuse cortical dysfunction suggestive of a delirium.

Five older patients aged 59–68 were also tested (patients 9–13 in table 1). One of these, patient 12, had a record within normal limits. The other 4 patients all had elevated impairment indexes (0.7–0.9). While older subjects commonly have some elevation in impairment indexes (23), it was our judgment that these 4 patients manifested mild cognitive impairment beyond that which could be explained by their age alone. In none of their records was there consistent evidence for focal or asymmetric cortical dysfunction; rather, they seemed to have mild diffuse cortical dysfunction of a type often seen in mild states of delirium.

The trend toward elevated impairment indexes among the 5 oldest patients is highly significant in comparison with the 8 younger patients ($p<.005$, two-tailed Mann-Whitney U test). A comparison of the mean data for the two groups (table 1) shows that there are no differences in daily dose, serum lithium level, duration of lithium therapy, education level, or WAIS full-scale IQ. Thus the exposure of both groups to lithium carbonate is comparable. In addition to the age difference and the aforementioned difference in scores on the Halstead impairment index, the older patients have suffered from manic-depressive illness for almost 20 more years.

DISCUSSION

Many psychiatric investigations using the Halstead battery are restricted to subjects 55 or 60 years of age because older subjects sometimes exhibit cognitive impairment or cortical dysfunction secondary to the

aging process or to various systemic medical diseases. On the other hand, the Halstead index is a fairly sensitive indicator of neuropsychological function for nonelderly subjects.

Among 8 patients younger than 55 maintained on lithium therapy for several years, 7 exhibited no evidence of impaired cortical function on the Halstead battery. The eighth patient was essentially normal, although his performance on four Halstead subtests was very slightly abnormal. To our knowledge, no other retrospective studies of possible long-term effects of lithium carbonate on cortical function have been reported. Like all retrospective studies, this one lacks baseline data that would permit pre- and posttreatment comparisons. In this regard, it is impossible to evaluate the significance of the abnormal EEG observed in 1 patient because a baseline EEG was not obtained before treatment was initiated. The data strongly suggest, however, that patients maintained on lithium carbonate do not exhibit cortical dysfunction after years of treatment.

Results for the 5 patients older than 55 are much more difficult to interpret. It is impossible to judge whether their elevated Halstead indexes were secondary to lithium or some other cause. Older patients are well-known to be more susceptible to the deliriogenic effects of many agents (e.g., general anesthetics, benzodiazepines, anticholinergics), and this may be the case with lithium as well. It might follow that older patients would also be more susceptible to structural CNS changes secondary to lithium toxicity, although we know of no data on this issue. Finally, it may be that subtle cognitive impairment is a natural consequence that follows decades of manic-depressive illness with or without lithium therapy. We know of no data that address this interesting question. Whatever the reason, lithium is no exception to the axiom that therapeutic agents require careful monitoring in older patients.

Although we realize that this report may be added to the growing list of published warnings about the dangers of lithium, we have not submitted these results as an admonition. Rather, we are impressed by the lack of CNS consequences observed among the 8 younger patients after years of lithium therapy. Questions raised by data such as these must remain unanswered, however, until prospective studies are launched to study the relative safety of long-term treatment with lithium carbonate.

Focused Psychiatric Curriculum Selection: Student, Psychiatrist, and Nonpsychiatrist Physician Expectations

BY WARNER JOHNSON, M.D., JOHN SNIBBE, PH.D., KAAREN HOFFMAN, PH.D., AND LEONARD EVANS, PH.D.

The authors obtained curriculum needs analysis data from second-year medical students and compared these with data obtained from nonpsychiatrist physicians and psychiatrists. All groups felt that interviewing skills, the doctor-patient relationship, managing the dying patient, and evaluation of suicidal patients were important topics. All gave psychological testing, behavior modification, mental retardation, and psychoanalytic theory the lowest teaching priority. The students gave a higher rating to all topics than did the other groups. The authors suggest that this kind of analysis can facilitate curriculum selection and implementation.

PSYCHIATRIC EDUCATORS have shown increasing interest in applying modern educational principles to their instructional programs for medical students. As a reflection of this interest, a number of papers on psychiatric teaching goals and specific curriculum content have been published (1–5).

In 1975, after failing to find consensus in the literature about the composition of a psychiatric curriculum for medical students, two of us (W.J. and J.S.) (6) undertook a study to objectify course selection. Our study provided data on the relative importance of 21 commonly taught psychiatric topic areas as perceived by 131 mental health professionals and nonpsychiatrist physicians. In the same year Bowden and Barton (7) published a comprehensive paper outlining topical material for an entire psychiatric curriculum that they considered essential to the education of medical students. Their outline represented a composite of ideas derived from the literature, a survey of subjects commonly taught at a number of medical schools, and a synthesis of their own ideas.

Significantly, the topics mentioned in Bowden and Barton's study were similar to those we investigated. The former study outlined a carefully thought-out psychiatric curriculum as defined by educators, and the latter provided some objective data on the relative importance of specific teaching topics as evaluated by

The authors are with the University of Southern California School of Medicine, 2025 Zonal Ave., Los Angeles, Calif. 90033. practicing professionals. A review of these papers will provide designers of curricula contemporary ideas about what should comprise instruction for medical students. However, we feel that data from an additional source should be included during curriculum planning to assure optimum sequencing, relevance, and acceptance of instruction for the students. Along with others (8–10), we feel that an additional source of curriculum data can come from the students themselves, who are the immediate consumers of the instructional program.

It can be argued with some justification that most medical students do not possess the knowledge or experience that would enable them to make meaningful judgments about the future relevance of the subject matter they are taught. However, medical students do have opinions and expectations about the curriculum that affect their learning. We believe it is useful for the educator to be apprised of student opinions and, accordingly, to make allowances for them within the structure of the curriculum as it is being designed. Instruction is likely to proceed more smoothly when students know what is expected of them and when they can perceive the relevance of the material to be learned. If the course expectations are similar for students and teachers, the educational process can proceed with fewer difficulties. On the other hand, if the teacher and students have disparate opinions about the relevance or sequencing of the subjects taught, the educational process may evoke needless anxiety, confusion, or negativism in the students. In order to alleviate these problems the students may need special orientation about the nature, relevance, and sequencing of course work before actual instruction begins.

We hypothesize that there may well be differences between instructor and student expectations about psychiatric course work. If such discrepancies exist, it is good to know about them and plan accordingly. This paper describes our attempt to evaluate and compare student ideas of psychiatric course work material with those of practicing physicians and psychiatrists. We hope this comparison provides a means of improving the instructional process.

METHOD

For our 1975 study (6) we developed a questionnaire that asked, "What specific psychiatric information and skills should a nonpsychiatrist physician have?" The questionnaire contained 21 psychiatric topics commonly taught to medical students. Respondents were asked to rate the relative importance of the topics by assigning one of the following designations to each: not at all important, moderately important, very important, and essential.

We distributed a total of 185 of these questionnaires to a sample of faculty members at the University of Southern California School of Medicine, faculty members at the school's Department of Psychiatry and Division of Psychology, the staff of two local psychiatric hospitals, and the staff of a private general hospital. Completed questionnaires were received from 18 clinical psychologists, all of whom had Ph.D. degrees; 48 psychiatrists; and 65 nonpsychiatrist physicians. Two-thirds of the mental health professionals were involved in the education of medical students and/or residents. Approximately two-thirds of the nonpsychiatrist physicians were pediatricians, internists, and family physicians. The remaining third practiced various surgical specialties. All but 2 of the nonpsychiatrist respondents were regularly involved in providing direct or indirect patient care.

For purposes of the current study the same questionnaire was distributed to second-year medical students during the orientation session for their first presentation in psychiatry, an introductory course in psychopathology. Student data were gathered for two successive years, 1974 and 1975, and the results obtained were compared with the data collected from the psychiatrists and nonpsychiatrist physicians surveyed in 1975 (6).

RESULTS

Complete data were collected from 88 second-year students in the fall of 1974 and from 108 students in the fall of 1975. The two student groups were very similar in their responses. A significant difference between the ratings of the two groups was found for only 1 of the 21 topic areas. The students in 1975 rated an awareness of psychodynamic principles in evaluating a patient's behavior as significantly more important than did the students in 1974 ($t=-3.63$, $p<.01$). The remaining 20 topic areas were rated the same in importance by the two student groups. Because the two student groups were highly similar, their responses were pooled to form a single group for statistical comparisons with the psychiatrists and the nonpsychiatrist physicians surveyed in 1975.

Table 1 presents the mean rating of importance given to each topic area by each of the three groups. The rank order of the topic areas for each group was obtained from the mean ratings. The rankings of the topic areas listed on the right side of table 1 indicate the feeling of each group about the relative importance of each topic in relationship to the others. Kendall's coefficient of concordance for the three rank orders is .92, indicating a high degree of similarity among the three groups. This similarity is particularly remarkable as one examines the 5 topic areas considered most and least important by the three groups.

Four of the 5 topic areas considered most important by psychiatrists, nonpsychiatrist physicians, and students are identical. Specifically, all groups ranked the following among the 5 most important topic areas: the ability to talk with patients about their personal problems, an understanding of the emotional aspects of the chronically ill or dying patient, familiarity with the dy-

TABLE 1
Mean Ratings of Importance and Ranks of 21 Psychiatric Topics by Psychiatrists (N=48), Nonpsychiatrist Physicians (N=65), and Medical Students (N=196)

Information or Skill	Ratings*						Ranks**		
	Psychiatrists		Nonpsychiatrist Physicians		Students				
	Mean	SD	Mean	SD	Mean	SD	Psychiatrists	Nonpsychiatrist Physicians	Students
The ability to talk with patients about their personal problems	3.62	.64	3.61	.72	3.86	.42	1	1	1
The ability to distinguish among psychosis, neurosis, organic brain conditions, and character disorders	2.93	.80	3.12	.85	3.38	.72	9	3	9
A working knowledge of the community resources available for the care of emotionally disturbed individuals	2.68	.80	2.53	.83	3.54	.64	11	12	6
An awareness of psychodynamic principles in evaluating a patient's behavior	2.08	.67	2.46	.86	2.84	.89	17	13	15
The ability to evaluate a patient's potential for suicidal or destructive behavior or need for psychiatric hospitalization	3.38	.73	3.06	.89	3.57	.61	4	5	5
An awareness of when and how to refer a patient to a psychiatrist	3.47	.65	2.86	.89	3.59	.61	2	7	4

Basic knowledge of current psychiatric treatment modalities	2.10	.66	2.20	.79	2.59	.76	16	16.5	18.5
An understanding of normal personality development	2.43	.74	2.38	.84	3.12	.73	12	15	12
An understanding of the principles of psychoanalytic theory	1.50	.58	1.72	.83	2.14	.75	20	21	21
The ability to diagnose and treat family and marital disturbances	2.12	.67	2.66	.85	2.91	.76	15	10.5	14
A working knowledge of common psychopharmacological medications	3.14	.71	2.84	.85	3.09	.78	6	8	13
An understanding of sexual problems and their management	2.75	.69	2.66	.85	3.36	.65	10	10.5	10
The ability to diagnose and manage the mentally retarded	1.91	.79	1.87	.89	2.63	.80	18	20	17
Familiarity with the principles of behavior modification	1.54	.54	2.01	.83	2.59	.74	19	18	18.5
An understanding of the physiological comcomitants of emotional stress	3.02	.66	2.90	.93	3.39	.69	7	6	8
Familiarity with the dynamics of the doctor-patient relationship	3.31	.72	3.13	.80	3.62	.58	5	2	3
An understanding of the emotional aspects of the chronically ill or dying patient	3.41	.57	3.10	.81	3.67	.49	3	4	2
Familiarity with the major types and uses of psychological tests	1.41	.53	1.98	.80	2.39	.75	21	19	20
An understanding of the common behavior disorders of children and adolescents	2.31	.62	2.41	.86	3.17	.72	13	14	11
A basic knowledge of alcohol and drug abuse	2.97	.75	2.84	.73	3.48	.61	8	9	7

*The rating system is as follows: 1=not at all important, 2=moderately important, 3=very important, and 4=essential.
**1=topic considered most important; 21=topic considered least important.

namics of the doctor-patient relationship, and the ability to evaluate a patient's potential for suicidal or destructive behavior or need for psychiatric hospitalization.

The groups also agreed that the following topic areas were among the 5 least important to learn: an understanding of the principles of psychoanalytic theory, familiarity with the major types and uses of psychologi-

cal tests, familiarity with the principles of behavior modification, and the ability to diagnose and manage the mentally retarded.

Data derived from the comparison of rank orders can be deceptive if differences in absolute value are ignored. For example, all groups ranked in approximately 10th position an understanding of sexual problems and their management. However, an inspection of the actual mean ratings for each group shows that they range from 2.66 for nonpsychiatrist physicians to 3.36 for students.

Table 1 shows that despite the similarities in the rank ordering of topics, the three groups differ in absolute ratings. Most striking is that the students perceived every topic as more important than either the psychiatrists or the nonpsychiatrist physicians. The average rating of the students over all 21 topic areas is 3.12, compared with 2.58 for the psychiatrists and 2.59 for the nonpsychiatrist physicians. On the average, the students perceived the 21 topics as very important, but the psychiatrists and nonpsychiatrist physicians on the average perceived the topics falling midway between moderately and very important. Analyses of variance performed on each question showed that a significant difference in mean rating ($p<.05$) was present for 20 of the 21 topic areas. The only topic area for which the three groups expressed similar mean ratings was a working knowledge of common psychopharmacological medications. Students, psychiatrists, and nonpsychiatrist physicians all rated this topic close to very important.

It is clear that before further comparison of the similarities and/or differences among the ratings of the three groups, one must control for the differences noted in actual mean value. To accomplish this, each person's ratings were converted to standard scores pivoting around that particular individual's mean rating for all 21 topics. These transformed scores represent the relative value a topic had for a particular individual (an ipsative measure).

Analyses of variance of the transformed scores were performed to detect any significant differences in the relative positioning of each topic area by the students, psychiatrists, and nonpsychiatrist physicians. The average standard scores for all topics for each group are available on request. Significant differences were found for 7 of the 21 topic areas. Specifically, the students were inclined to rate a working knowledge of the community resources available for the care of emotionally disturbed individuals and an understanding of the common behavior disorders of children and adolescents as relatively more important than either psychiatrists or nonpsychiatrist physicians. Psychiatrists tended to rate an awareness of when and how to refer a patient to a psychiatrist and a working knowledge of common psychopharmacological medications as relatively more important than did the other two groups. Nonpsychiatrist physicians tended to view the ability to diagnose and treat family and marital disturbances as relatively more important than the students or the psychiatrists. Finally, although all three groups judged familiarity with the principles of behavior modification and familiarity with the major types and uses of psychological tests as unimportant, the psychiatrists rated these topics significantly lower than did either the students or the nonpsychiatrist physicians.

DISCUSSION

This study was undertaken to refine further the selection of psychiatric topics potentially important for medical students to learn by examining the opinions of mental health professionals, nonpsychiatrist physicians, and students. We believe that the selection of a curriculum based on broad consensus, including that of the students, is more likely to result in a relevant and acceptable course. Specifically, this project aided in establishing the rank order of topics for each of the three groups, identifying those topics most important for inclusion in a psychiatric curriculum, and indicating those topics for which pre-instruction preparation may be needed.

The major findings indicated a remarkable similarity among all three groups in their selection of the most and least important topics. An examination of these data should enable psychiatric educators to select a core curriculum that meets both the future needs of the students and their current expectations. However, significant differences were found in the absolute value that the groups placed on various topics. For example, the students tended to rate all of the topics as more important than did the professional groups. Although the high student ratings may be partially attributed to a lack of knowledgeable discrimination, their judgment may also indicate an acceptance of and perhaps enthusiasm for psychiatric instruction. Every effort should be made by means of thoughtful curriculum planning and implementation to maintain this high expectation.

In spite of consensus on most topics, the unique curriculum interests of each of the three groups is noteworthy. It would be well for psychiatric educators to respond to these stated expectations in some constructive fashion during curriculum development and implementation. For example, in any given curriculum one could elect to include only those topic areas ranked high by all groups. Such an approach would give reasonable assurance that student receptivity and topic relevance would be optimal. However, for cogent reasons a curriculum should anticipate possible future needs as well as those presently recognized. It may be quite appropriate, therefore, to include topic areas that are not currently perceived as important by the students. In such an instance, the results of the needs analysis serve to alert one to the importance of special student preparation by demonstrating the future relevance of the topic area and the need to change current attitudes. The recognition and discussion of the discrepancy between currently felt curriculum needs and possible future requirements will help greatly in dis-

pelling the attitudes about psychiatric education held by many physicians, that it is "poorly taught and irrelevant to the needs of medical practice" (11).

Juvenile Court Versus Child Guidance Referral: Psychosocial and Parental Factors

BY SHELLEY S. SHANOK, M.P.H., AND DOROTHY OTNOW LEWIS, M.D.

The authors compared the psychiatric symptoms, socioeconomic status, family structure, family size, and occurrence of treated parental mental illness in 136 children referred to a juvenile court and 82 children referred to a child guidance clinic. The prevalence of psychiatric and organic symptoms and treated parental psychopathology in both groups of children did not differ significantly. Juvenile court clinic children, however, tended to come from larger families and to lack a biological mother in the home. The authors explore explanations for the routing of sick children to the juvenile court rather than to a treatment facility.

THE PURPOSE of this paper is to report the results of a study comparing the psychiatric symptoms, socioeconomic class, and family constellation of children referred to a juvenile court psychiatric clinic and of children referred to a child guidance clinic from the same geographic area. We will also compare the psychiatric status of parents of children in the two groups as reflected in psychiatric treatment records. Finally, we will explore possible reasons why certain children were referred to the juvenile court and then to its psychiatric clinic, whereas other children with similar symptoms and behaviors were recognized as being psychiatrically disturbed rather than predominantly delinquent and were referred to a child guidance clinic.

LITERATURE

The fact that the first child guidance clinic in the United States was founded to aid the juvenile court in Chicago (1) indicates an early recognition that many children who came in conflict with the law had psychiatric problems. In recent years, such investigators as Stephenson and associates (2), Warren (3), and Bennett (4) have expressed again the view that delinquent children resemble children with diagnosed psychiatric disorder. However, most of the psychiatric literature on delinquent children has stressed findings of characterological or neurotic disturbances. Serious psychiatric symptoms such as psychotic symptoms have been reported to be rare (5, 6).

On the other hand, although psychotic disorders have rarely been reported in delinquent populations, longitudinal and retrospective studies have docu-

mented the existence of psychotic disorders, particularly schizophrenia, in adults who were delinquent as children (7–13). Furthermore, although some investigators have reported an association between organic dysfunction and antisocial behavior (14–16), others have found no greater prevalence of organic disorders in criminals than in other populations (17).

The present study comparing children referred to a juvenile court clinic with those referred to a child guidance clinic sprang from the observation that 25% of the first 40 children referred to the New Haven Juvenile Court Clinic displayed psychotic symptoms (18). In another study we found that 18 of 285 children seen at the court clinic over a two-year period demonstrated symptoms of psychomotor epilepsy in association with paranoid ideation and assaultive behavior (19). Further, we have found that parents of delinquent children were treated for psychiatric impairment significantly more often than were other individuals in a lower-class population of New Haven and more often than the general population of Connecticut (20). Having noted serious psychopathology in children referred to a court clinic and in their parents, we wondered in what ways these children and their families resembled or differed from those seen in child guidance clinics. To this end our research was directed.

METHOD

Our sample consisted of all of the children between the ages of 7 and 16 who had been referred for evaluation to the New Haven Juvenile Court Clinic during a one-year period in the early 1970s (N=136; there were 90 boys and 46 girls). Our comparison sample consisted of all of the children between the ages of 7 and 16 who had been referred to a child guidance clinic in the same vicinity during the same target year (N=82; there were 58 boys and 24 girls).

The court clinic children studied were somewhat younger and had committed more offenses than the general court population, but they were similar to the general court population with respect to social class, race, sex distribution, and occurrence of treated parental psychopathology. The methodology for these comparisons has been reported elsewhere (21).

Psychiatric Symptoms and Demographic Characteristics

Psychiatric and demographic data were gathered from clinical records at the child guidance clinic and from juvenile court and court clinic records. Because the children did not always fit into hard and fast diagnostic categories, psychiatric information at the juvenile court was recorded in terms of symptoms rather than diagnoses. Psychiatric symptoms were initially recorded as neurotic, characterological, adjustment, psychotic, organic, or a combination of any of the above. For the purpose of data analysis, we divided the symptoms into three categories: 1) adjustment, characterological, and neurotic symptoms as one group, 2) psychotic symptoms, and 3) organic symptoms. A child could be categorized as demonstrating more than one kind of symptom.

Records at the child guidance clinic contained much descriptive information, but the children had not been assigned to symptom categories. Therefore, in the interest of obtaining comparable data and maintaining confidentiality of subjects, one of us (S.S.S.) abstracted each child's chart, taking down verbatim all references to symptoms. The abstracts were then reviewed independently by three experienced clinicians, two of whom were child psychiatrists and one a child psychologist. Each clinician noted the presence or absence of psychotic, organic, or what for the purposes of this study were considered less serious symptoms (e.g., adjustment, characterological, and neurotic).

All three clinicians agreed on the nature of the symptoms in 60% of all cases. There was agreement between at least two of the raters in an additional 37.5% of the cases, and there was no agreement in 2.5% of the cases. Thus there was agreement between at least two of the raters in 97.5% of all the cases. When there was no agreement among the raters, the child was classified as having no diagnosis. In cases in which two clinicians agreed, the child was assigned to the symptom categories agreed on by the two raters.

Measures of Parental Mental Illness

Parental mental illness was measured according to whether or not a parent had ever received treatment or had been hospitalized at one or more of the three state hospitals and/or the major hospital-based psychiatric facility in the geographic area of the study. Our study group consisted of 264 parents of juvenile court children (134 mothers and 130 fathers) and 158 parents of child guidance clinic children (82 mothers and 76 fathers). Mental illness was classified in terms of inpatient or outpatient care with the assumption that inpatient care reflected a more severe disturbance than outpatient care.

Information was also gathered on occupation of head of household, marital status, race, person(s) with whom the child was living, number of siblings in the household, and the child's sex. The Warner 7-Point Scale of Occupation was used to determine social class in both groups (22).

FINDINGS

The children in the juvenile court clinic and the children in the child guidance clinic had a similar prevalence of organic and psychotic symptoms. However, characterological, adjustment, or neurotic symptoms were noted significantly more often among children at the child guidance clinic (see table 1).

The difference between the proportion of parents in each group who had received any kind of psychiatric treatment was not significant. Similarly, when parental

TABLE 1
Psychiatric Symptoms in 136 Children Referred to a Juvenile Court Clinic and 82 Children Referred to a Child Guidance Clinic

treatment was analyzed separately in terms of inpatient and outpatient treatment, there were no significant differences. Furthermore, when the occurrence of maternal psychiatric treatment and paternal psychiatric treatment were compared separately, no significant differences were found (see table 2).

A comparison of social class, as reflected by the occupation of the head of each household, revealed a significant difference between the two groups of children. In the juvenile court clinic, 86% of the 86 families on whom information about occupation was available came from the lower four classes, compared with approximately 74% of 82 child guidance clinic families ($\chi^2=13.089$, df=6, $p<.05$).

At the juvenile court clinic, 50 of the 136 children (37%) came from intact homes in which their natural parents were married; 65 children (48%) came from broken homes in which parents were divorced, separated, single, or widowed; and 21 children (15%) came from homes in which insufficient data were available to determine the marital status of the parents. At the child guidance clinic, 41 of the 82 children (51%) came from intact homes, and 40 children (49%) came from broken homes. No significant difference was found between groups in relation to the marital status of parents ($\chi^2=.7078$, $p>.05$).

Although there was no difference between the groups in terms of married, separated, or divorced parents, a significantly greater proportion of the children living in homes without a biological mother were seen at the court clinic rather than the child guidance clinic. Twenty of 121 delinquents on whom data were available (17%) were motherless, compared with only 3 child guidance clinic children (4%) ($\chi^2=6.6904$, $p<.05$).

The family structure of our subjects was further explored to determine whether the juvenile court clinic families and the child guidance clinic families differed in size of family. Seventy-three of the 109 children for whom information was available in the juvenile court clinic (66%) had three or more siblings, compared with 24 of 82 children in the child guidance clinic (30%); this difference was significant ($\chi^2=26.00$, $p<.001$).

Because we knew that the two groups differed in social class we wondered whether the increased number of siblings among the delinquent children was related primarily to their lower social class. When social class was held constant, we still found that children in so-

cioeconomic classes 6 and 7 at the juvenile court clinic had significantly more siblings than did children in socioeconomic classes 6 and 7 at the child guidance clinic (class 6, $\chi^2=6.626$, $p<.05$; class 7, $\chi^2=5.235$, $p<.05$).

DISCUSSION

The major finding of this study was that children seen in the juvenile court clinic demonstrated psychotic and/or organic symptoms similar in nature to the symptoms of children seen at a child guidance clinic. Thus the juvenile court clinic appeared to be a repository for many extremely disturbed children.

Since the occurrence of parental psychiatric treatment was also similar in both groups, neither a child's severe psychiatric symptoms nor his or her parents' psychopathology could explain why a child found himself or herself in a juvenile court clinic rather than in a more appropriate child psychiatric facility.

Social class and family size were two factors that helped to explain the difference in referral. Court children tended to come from lower social classes and larger families. Nevertheless, the great majority of the children in both groups were from the more deprived sectors of the community. Our most striking finding was the difference in proportions of motherless children in the juvenile court clinic population compared with the child guidance clinic population. Although the proportions of broken homes were similar, there were more motherless children or children living with stepmothers in the juvenile court clinic than in the child guidance clinic.

These findings suggest that when a natural mother is not present there may be nobody to protect the best interests of the psychiatrically disturbed child and direct him or her to a therapeutic rather than a correctional facility. These findings are consistent with our earlier findings comparing adopted and neglected children seen in the juvenile court clinic (23). We found that adopted children referred to the court clinic were more likely to be sent to training schools than were so-called neglected children with natural parents, even though the latter group of children had committed more frequent and more serious delinquent acts. Natural parents seemed to mobilize far greater resources to keep their delinquent children from training schools than parents of adopted delinquent children.

The present study suggests that in homes without a biological mother, fathers may be unable to take on an effective mothering role. They may not recognize the meaning of their child's behavior problems and may not get treatment for them. In cases in which there is a stepmother, her entrance into the home may be too late for an adequate reciprocal bond to form between the child and the surrogate mother. Attachment difficulties may be compounded in large families composed of natural children and stepchildren. In these homes mothers may lack an intense emotional commitment to a psychiatrically disturbed stepchild and lack an investment in protecting him or her from the legal consequences of delinquent acts by obtaining treatment in a psychiatric facility.

Fear of the Mentally Ill: Empirical Support for the Common Man's Response

BY JOHN M. LAGOS, PH.D., KENNETH PERLMUTTER, AND HERIBERT SAEXINGER, M.D.

The authors studied the hospital records of 400 hospitalized mentally ill patients for evidence of violent behavior leading to admission. They found that 36% of 321 admissions (excluding patients diagnosed as having a personality disorder or as drug- and/or alcohol-dependent) were preceded by some form of violent, fear-inspiring behavior. They suggest that mental health professionals deal with the general public's fear of the mentally ill on the basis of such findings rather than dismiss it as illogical.

THE PUBLIC'S FEAR of the mentally ill is well known. Among mental health professionals this fear is generally considered to be unfounded, and there is ample support for that contention. In their review of research on the subject, Rappeport and associates (1) concluded, "Crime rates are not higher among ex-mental patients than among corresponding persons in the general population; indications are that the reverse is true" (p. 76). Despite such evidence, the common man remains unconvinced (2).

Some authors account for the persistence of this fear by hypothesized psychodynamics of the general population and the social functions of belief systems (3–5). Such explanations make very thoughtful contributions to our understanding of this phenomenon, but, compelling as they may be, explanations are no substitute for facts, and one cannot help but wonder if all the facts have been gathered. Every study concluding that the mentally ill are not dangerous has gone to police records to seek its data. Perhaps an alternative data source would yield facts that suggest different conclusions.

We approached the question of violence among the mentally ill by examining hospital records of psychiatric admissions. The purpose of this study was to determine how frequently people behave violently when they become mentally ill.

Dr. Lagos is Clinical Assistant Professor, College of Medicine and Dentistry of New Jersey, Newark, N.J. Mr. Perlmutter is a doctoral candidate in clinical psychology, Emory University, Atlanta, Ga. METHOD

We randomly selected the records of 100 patients admitted during 1974 to each of 4 psychiatric facilities in New Jersey. We reviewed the admission notes for these 400 patients for any description of patient behavior that might be construed as violent. The described behavior had to be recent and presented as part of the basis for admission. Appendix 1 contains a list of the categories of violent behaviors presented in descending order of severity and/or specificity. These categories were used in tabulating the behavioral descriptions obtained from patient records. If a given record presented more than one description that might have been placed in more than one category, only the most serious description was tabulated. Thus there was only one entry per patient.

RESULTS

The data revealed that 37.7% of the 400 admissions sampled manifested some form of violent behavior. Twenty percent of the sample were specifically described as acting in a physically violent way toward persons or objects, and another 11% were vaguely described as acting violently. Because those in the ambiguous category may also have attacked persons or objects, somewhere between 20% and 31% of the population sample may be said to have acted violently in a physical way toward persons or objects.

We thought it possible that these statistics on violent behavior just before psychiatric hospitalization might have been inflated by the inclusion of patients who were not mentally ill according to the most common use of that term.[1] Therefore, we removed the data on individuals who carried a diagnosis of personality disorder or whose primary discharge diagnosis indicated the presence of a toxic condition due to alcohol or drugs. Table 1 shows that 35.8% of the remaining sample (N=321) manifested some form of violent behavior; 18.1% of these were specifically described as

[1]The layman typically distinguishes among those who act irrationally because they have undesirable or deficient characters, those who act irrationally because they have been taking alcohol or drugs, and those who act irrationally because they are "not in their right mind." Only the latter are generally thought of as mentally ill.

All female patients	44	38.3	176	54.9

acting in a physically violent way toward persons or objects, and 10.9% were vaguely described as acting violently. Thus between 18% and 29% of those defined as mentally ill according to the common use of the term acted in a physically violent way toward persons or objects.

Because 45.2% of the sample were black, we tabulated the statistics to determine if the overrepresentation of one ethnic group or the underrepresentation of another had biased the results. According to the data presented in table 2, no one of the three ethnic groups identified contributed to the total number of patients with violent behaviors in greater proportion than its proportion in the sample would warrant. Of the 115 mentally ill patients whose records showed violent behavior (see table 2), only 3 (2.6%) were arrested.

DISCUSSION

Are the mentally ill to be feared or not? This is a terribly practical question in our era of community treatment. If mental patients are to be helped by this contemporary approach, communities must accept them. However, if communities fear the mentally ill they are likely to reject them. The mental health professions seem to approach the problem of community fear from the stance that mental patients are not dangerous, fearing them is irrational, and more community education is necessary to dispell the anxiety and prejudice. The persistence of the general fear of the mentally ill compells us to reexamine this stance.

There are two sources of support for the contention of mental health professionals that mental patients are neither dangerous nor to be feared: research data and clinical experience. The earlier research studies (6–9) reported that the mentally ill are less likely to be violent than the general population. More recent findings (10–13) do not support the proposition that the mentally ill are *less* likely to be violent than the general population, but they do not offer any firm support for the belief that mental patients are *more* likely to be violent either.

Rappeport and Lassen (10, 11) found that female patients had a significantly higher arrest rate for aggravated assault than the general population and that male patients had a significantly higher arrest rate for robbery. We question the validity of these findings on the basis of the fact that patients with a diagnosis of alcoholic intoxication accounted for a third of the arrests in their sample. Alcoholic intoxication does not qualify for the classification of mentally ill as the category is most commonly defined. Giovannoni and Gurel (12), who studied a population that was 95% schizophrenic, found that ex-patients had higher arrest rates for the crimes of homicide, assault, and robbery than the general population. However, they did not test the statistical significance of these differences, and the very small numbers involved (i.e., 3 homicides, 7 assaults, and 3 robberies) make statistical significance unlikely. Zitrin

and associates (13) found that the psychiatric patients in their study had arrest rates for violent crimes (i.e., rape, robbery, aggravated assault, and burglary) higher than the corresponding rates in their community. Once again, however, the differences were not tested for statistical significance, and the removal of data on subjects with a diagnosis of alcoholism or drug dependence reduces the arrest rates for the patients to a parity with community rates.

The consistency with which research has found mental patients to be as harmless as the general public is matched by the consistency with which these investigations have used arrest records as the operational definition of dangerousness and violence. Undoubtedly this operational definition covers the most serious fear-inspiring behaviors. However, there are many less serious acts of violence that are quite capable of inspiring fear. Clearly, the average person cannot be expected to remain calm and comfortable in the face of a threat, irrational anger, the destruction of objects, or mild physical assault. Moreover, such behavior, especially in someone termed "ill," seldom results in formal charges (14). Therefore, by investigating only extremes of violence, research on the dangerousness of the mentally ill limits itself to a partial answer to the question. This partial answer does not provide a scientific basis for declaring that the public's fear of the mentally ill is irrational.

In broadening our scope to include less serious acts of violence, our study found that 36% of 321 psychiatric admissions were preceded by some form of violent, fear-inspiring behavior. If criminal arrest had been used as the criterion of violence the rate of violent behaviors for this sample would have been 9 per 1,000 because only 3 patients in the sample had been arrested. Given our very broad operational definition of violence, however, the rate of violent behaviors was found to be 360 per 1,000: a fortyfold increase. These data provide no comparisons with the general population and therefore cannot substantiate the proposition that ex-mental patients are more violent than the general public. Nevertheless, these data do indicate that there may be considerable violence in behavior associated with mental and emotional breakdowns. Perhaps this is what the public responds to with fear.

The clinical experience of mental health professionals is also cited in support of the proposition that the mentally ill are not to be feared. The great majority of mental health professionals have never been injured by the people they treat (15). Indeed, skillful psychiatric personnel are able to handle patients' anger and irrationality with such efficiency that they are inclined to be puzzled or amused by the anxiety and clumsiness of the layman faced with such a situation. What is easily overlooked, however, is the supporting organization and the training and experience that make the professional's confident posture possible (16). If the clinician were to make a more complete statement on the matter, he or she would say that one need not fear the mentally ill *if* one learns to identify those whose condition leaves them vulnerable to violent outbursts, and *if* one learns how to handle that subgroup of vulnerable patients, and *if* one can count on assistance in an emergency.

Supporting data for the current posture of the mental health professions on the issue of public fear of ex-mental patients are sorely lacking. One cannot be at all certain on the basis of the evidence that community fear of the mentally ill is irrational. Indeed, the data of this study provide empirical support for the opposite view: that it is quite reasonable to fear the mentally ill. Therefore, we suggest that community education programs, which were designed to teach the public that there is no reason to fear the mentally ill, have failed because what they are teaching is not sufficiently accurate.

Community fear of the mentally ill clearly presents a problem. However, the problem may lie not in the fact that people fear mental patients but in the fact that the public fears them too much, under the wrong circumstances, or for the wrong reasons. Perhaps the solution to the problem lies not in telling the public that it is wrong to fear the mentally ill but in telling them to what extent ex-patients ought to be feared, under what circumstances or for what reasons they ought to be feared, or how one ought to respond when a patient is frightening. In order to provide such specific information, however, the area under investigation must be considerably broadened from its current narrow focus on arrest records.

If further research should show, as this study suggests, that there is some factual basis for fearing the mentally ill, it remains to be seen how this would affect the community approach to treatment. One can never be sure of such things, but being informed of a specific, realistic basis for fearing ex-patients might well do more to eliminate irrational fears than a hundred reassurances.

APPENDIX 1
Categories of Violent Behaviors

Attacks on persons: specific mention of physical assault on people, including hitting, pushing, choking, etc.

Attacks on objects: specific mention of physical assault on nonhuman entities, including throwing things, breaking things, physically abusing animals, etc.

Threats to persons: specific mention of stated intention or described act that communicated the distinct possibility of inflicting harm on another person

Verbal attacks on persons: specific mention of verbal behavior that, although not explicitly threatening, was nevertheless pointedly abusive and hostile

Ambiguous violence: vague, nonspecific description of behavior as "violent," "aggressive behavior," "uncontrollable," "hostile," etc. (ranked below the others because of lack of specificity)

Loss of impulse control: behavior described by such words as "running wildly," "yelling," "shouting," etc., and giving no indication of this activity's being directed at persons or objects

Briquet's Syndrome, Hysterical Personality, and the MMPI

BY BARRY I. LISKOW, M.D., PAULA CLAYTON, M.D., ROBERT WOODRUFF, M.D., SAMUEL GUZE, M.D., AND ROBERT CLONINGER, M.D.

The authors compared the MMPI scores of 29 inpatients diagnosed by other authors as having hysterical personality and 21 outpatients diagnosed by the authors as having Briquet's syndrome. The two groups of patients differed significantly in age, on the MMPI lie scale, and on the MMPI hypochondriasis scale but not on any of the other MMPI scales. The authors discuss the implications of these findings for further defining the differences and similarities between hysterical personality and Briquet's syndrome.

THE CONCEPTUALIZATION in 1951 by Purtell and associates (1) of an idea suggested by Briquet's work on hysteria in 1859 and Saville's in 1909 has had an increasing influence on current concepts of hysteria. The work of Purtell and associates was resumed by Perley and Guze in 1962 (2) and has been continued to the present day by Guze and associates at Washington University, St. Louis, Mo. This group has carried out many studies using the following diagnostic criteria for hysteria: the presence of a complicated or dramatic medical history; onset before age 35; and a minimum of 25 out of 59 medically unexplainable symptoms spread across 9 out of 10 symptom groups (all of these symptoms must have interfered with the patient's ability to function) (3). With this definition, the Washington University group delineated the difference between Briquet's syndrome and isolated conversion symptoms, verified the diagnostic stability of Briquet's syndrome as demonstrated by follow-up studies (4), and related it to other psychiatric disorders through family studies (5–8).

Attacks on this concept of hysteria have come from various sources. The most predominant is disagreement over equating the historically broad concept of hysteria with the more precise but more narrow concept of Briquet's syndrome (9). This semantic confusion regarding the definition of hysteria has led the

Dr. Liskow is Chief, Psychiatry Service, Veterans Administration Hospital, Iowa City, Iowa 52240. He is also Assistant Professor of Psychiatry, University of Iowa School of Medicine, Iowa City, Iowa. Dr. Clayton is Professor of Psychiatry, Dr. Woodruff is Professor of Psychiatry, Dr. Guze is Professor and Chairman, Department of Psychiatry, and Dr. Cloninger is Assistant Professor of Psychiatry, Washington University School of Medicine, St. Louis, Mo.

Washington University group in the last several years to use the term "Briquet's syndrome" in place of the term "hysteria" (4). In 1974 Chodoff, who is not from Washington University, suggested that Briquet's syndrome be considered separately from all other concepts related to hysteria (9). This would necessitate its separation from hysterical personality; hysterical neurosis, conversion type; and hysterical neurosis, dissociative type. According to the report of APA's Committee on Nomenclature and Statistics presented at the May 1975 annual meeting in Detroit, Mich., such a proposal was under consideration for *DSM-III*.

The separation of *DSM-II*'s diagnosis of hysterical personality (10) and Briquet's syndrome as distinct concepts has been seriously questioned. Kimble and associates found that 9 out of 10 women independently diagnosed as having hysterical personality also fulfilled criteria for Briquet's syndrome (11). They concluded that the *DSM-II* diagnosis of hysterical personality selected patients who were very similar to those diagnosed as having Briquet's syndrome. This similarity is not to be expected a priori, considering that hysterical personality is defined in *DSM-II* as "behavior patterns . . . characterized by excitability, emotional instability, over-reactivity, and self-dramatization . . . often seductive . . . immature, self-centered, often vain, and usually dependent on others" (10), and the definition of Briquet's syndrome is based on medical complaints without evident organic basis. Kimble and associates' findings suggest that the two diagnoses describe different phenomenological aspects of the same psychiatric illness.

Another approach to studying the relationship between hysterical personality and Briquet's syndrome is to give the same objective psychological test to groups diagnosed independently as having either hysterical personality or Briquet's syndrome and to look for similarities and/or differences in the results of the test. Slavney and McHugh (12) reported a study of 29 inpatients (26 women and 3 men) diagnosed as having hysterical personality. They administered the MMPI to these 29 inpatients. We compared Slavney and McHugh's MMPI results with our MMPI results for 21 patients diagnosed as having Briquet's syndrome. Our purpose was to determine whether the MMPI could be of value in defining the relationship between patients with hysterical personality and those with Briquet's syndrome.

METHOD

We contacted 29 patients diagnosed as having Briquet's syndrome in the Washington University Psychiatry Outpatient Clinic and asked them to come to the clinic to take the MMPI; each of the patients received $10. One of us (P.C.) reviewed each chart carefully and eliminated from the study all patients who were suspected of having another psychiatric illness or who did not meet the criteria for Briquet's syndrome. This process left 22 patients. One of these patients was eliminated because of failure to complete the MMPI, leaving a final total of 21 patients, all of whom were women. The MMPI data for these patients were compared with Slavney and McHugh's data on the MMPI's 3 validity scales and 10 clinical scales. We also compared the mean age of both groups of patients.

RESULTS

The ages and the MMPI K-corrected T scores for the 21 patients with Briquet's syndrome and for Slavney and McHugh's 29 patients with hysterical personality are shown in table 1. There is a significant difference in age between the patients with hysterical personality and those with Briquet's syndrome; the patients with hysterical personality were younger. Patients with Briquet's syndrome demonstrated abnormality (T score of 70 or above; i.e., T score of 2 standard deviations above normal) on 7 of the 10 clinical scales and 1 of the 3 validity scales. However, there were no significant differences on these scales between patients with Briquet's syndrome and patients with hysterical personality except for the hypochondriasis scale and the lie scale. This is of interest because the hypochondriasis scale is composed of 33 items, most of which relate to a variety of overt bodily complaints similar but not identical to the 59 symptoms used in making the diagnosis of Briquet's syndrome.

DISCUSSION

The fact that patients diagnosed as having Briquet's syndrome had markedly deviant MMPIs indicates the possibility of using the MMPI to screen for such patients. However, more work is needed to determine whether a stable MMPI pattern exists that can be distinguished from the pattern produced by other psychiatric disorders. The finding that Slavney and McHugh's patients with hysterical personality had deviant MMPIs similar to those of patients with Briquet's syndrome indicates the possibility that patients diagnosed as having hysterical personality are similar to or possibly indistinguishable from those diagnosed as having Briquet's syndrome. This possibility is given more credence by the study of Kimble and associates (11), which found that 9 patients with hysterical personality fulfilled criteria for Briquet's syndrome. Perhaps this finding should not be surprising, considering that in constructing the currently used criteria for Briquet's syndrome Perley and Guze (2) chose their subjects from a pool of patients who had been diagnosed as having hysteria, as had Purtell and associates (1).

The significant difference on the hypochondriasis scale between patients with Briquet's syndrome and those with hysterical personality suggests several pos-

sibilities. Patients with Briquet's syndrome might be a subgroup of the most seriously ill patients with hysterical personality or a subgroup of those whose emphasis on somatic complaints overshadows other aspects of their personality. Alternatively, in view of the significant age difference between the groups, the higher hypochondriasis score may reflect the natural progression of hysterical personality with increasing somatic complaints with increasing age. Age differences might also account for the significant difference in the lie scale.

These and other possibilities must remain speculative for the present, as must the precise relationship between hysterical personality and Briquet's syndrome. However, the MMPI may prove useful in resolving the problem noted by Kaminsky and Slavney of operationally defining nonmedical factors that might be useful in diagnosing and treating Briquet's syndrome (13). Finally, in a broader context, recent trends toward increasingly reliable psychiatric diagnosis might allow a more fruitful correlation of psychiatric diagnosis and objective psychological tests than has been possible.

Psychiatric Observations of State and Local Politicians

BY EDWARD MESSNER, M.D.

The author, a psychiatrist and an elected official in a small town, compares his observations of local politicians with a mental health commissioner's observations of politicians at the state level. The author feels that local politicians tend to be more strongly oriented toward relatively altruistic public service. Several factors, including personal ambition and reduced public scrutiny, may contribute to the apparently greater selfishness of politicians at the state level.

POLITICS HAS attracted the professional attention of psychiatrists from several points of view (1). Greenblatt (2) drew upon his experience as commissioner of mental health in Massachusetts to provide us with some observations by a psychiatrist who had been called upon to exercise considerable power in a state agency. He called attention to the scarcity of information and training available to individuals who sought executive careers in psychiatry.

In "Psychopolitics" Greenblatt (2) urged psychiatrists who have served in "powerful positions in the psychopolitical arena" to report and analyze their experiences. His purpose was to "teach us how to behave when fate thrusts such critical roles upon us." His invitation was thus not intended for me; but I offer this article as a response because I have participated in a complementary facet of political psychiatry (3). The purpose of this article is to provide some comparisons, contrasts, and inferences that may add to the body of knowledge about the interface between psychiatry and politics.

PERSPECTIVE ON THE FIELD OF POLITICAL PSYCHIATRY

In a review of previous publications on political psychiatry (1), I suggested a tentative classification of works on the subject. It listed the following topics:

1. Psychiatrists and theories related to government politics.
2. Psychiatrists and political activity.
3. Psychiatrists and radical political activity.
4. Community psychiatrists and political action.
5. Psychiatrists and international politics.
6. Psychiatrists in elective public office.

Greenblatt's recently published articles (2, 4, 5) fit most closely with the fourth group of publications, community psychiatrists and political activity. The richness of detail drawn from his experiences certainly expands that category markedly, as does his evaluation and analysis of those experiences. It would be appropriate to rename that domain of political psychiatry "psychopolitics."

In "Towards a Definition of Psychopolitics," Greenblatt (4) suggested that

> it might embrace the following areas: 1. The personality and psychology of the politician; his orientation to mental health workers and systems. . . . 2. The politics of the mental health worker. . . . 3. The relationships between political and mental health systems. . . . 4. The development of the political psychiatrist.

The present article focuses upon the "personality and psychology of the politician."

OBSERVATIONAL PERSPECTIVES

My political observations have been made primarily in the town of Amesbury, Mass., a partly rural community with a population of about 14,000 persons, located 40 miles north of Boston on the border with New Hampshire. Its economy is relatively depressed, with rates of unemployment higher and average income lower than the national average. Its various ethnic, racial, and religious groups live together harmoniously.

My experience consists of nearly six years of service as an elected public official—a politician—while continuing the clinical practice and teaching of psychiatry. As a member of the school committee[1] of a small town in Massachusetts, I have been a part-time, unpaid elected official with relatively little power and influence. This is in contrast to the full-time, salaried, appointed state officials, who exercise much greater power and influence as commissioners of mental health.

Dr. Messner is Assistant Clinical Professor of Psychiatry, Harvard Medical School, and Associate Psychiatrist, Massachusetts General Hospital, Boston, Mass. His address is Zero Emerson Place, Boston, Mass. 02114.

The author is grateful for the helpful suggestions of Charles Krauthammer, M.D.

[1]In most states the equivalent elected government body is known as a school board or board of education.

I do not have enough information to compare Amesbury politically with other towns, but it is an environment markedly different from the state capital. Greenblatt observed officials at the state capital, most of whom are full-time, paid, career politicians. My observations have been of small-town, part-time, primarily unpaid politicians. Most of them earn their living in other occupations.

OBSERVATIONS

It is no surprise that these two markedly different positions would produce experiences and observations at great variance with each other. Yet common themes such as public service, adversary relationships, and exposure to the news media tie them together. Much of what Greenblatt wrote in "Psychopolitics" (2) corresponds with some of my own political experiences.

Greenblatt (2) described politicians by comparing them with his professional colleagues. He wrote that they are "generally more open about their feelings, more extroverted, more anxious to do a favor and earn gratitude" than are physicians. It is difficult for me to discern any general differences regarding the openness and feelings of local politicians as compared with psychiatrists I have known. They may be more extroverted than most psychiatrists in that they seem to be more willing to speak in public. Politicians are willing to campaign for election, sometimes door-to-door, and to make public a part of their private lives.

Politicians are probably asked to do favors (6) more often than psychiatrists are. My observation is that local politicians, as a group, are probably somewhat more explicit than my medical colleagues in expressing—and in acting to attain or reject—their likes and dislikes. The difference is probably not so great as with the politicians observed by Greenblatt.

Politicians in a small town exemplify a wide range of educational, occupational, economic, intellectual, and social backgrounds. That breadth is bound to account for some important differences between them and groups of psychiatrists or other physicians. The medical groups are skewed toward extensive education, high intelligence, and relatively high socioeconomic levels. Greenblatt (2) observed that our professional colleagues' lives tend to be relatively "restrained and refined"; they are "more serious-minded and . . . [their] conduct and actions are guarded, especially in the social sphere"; and they tend to be "more intellectual and objective." My observations are consistent with his in these areas, but I sense a difference in degree. The politicians with whom I have had contact come closer to being a random selection of people—average citizens—than does the group of state legislators and other officials observed by Greenblatt. The small-town politicians are less "interested in grabbing power"; less intensely inclined toward "personal aggrandizement"; less mired in "narrow partisanship"; and far less likely to practice "duplicity."

The foregoing comparisons are largely matters of degree. However, there are also qualitative differences. For example, I have not at all been struck by an "atmosphere of suspiciousness, the assumption that everyone is motivated by base personal desires" (2). On the contrary, I have often been impressed by the many instances in which my fellow townspeople have extended themselves to serve our community. Most of the elected officials with whom I have had contact seemed to feel a sense of duty and responsibility to their constituents. It is more than a matter of winning their votes. They seem to care a great deal about the town and its residents.

The political system at the local level is fundamentally competitive and operates on adversary principles, just as it does at the state level. I have not observed it to be "a political jungle," as Greenblatt has observed on the state level. There seems to be a strong sense of community interest among town officials, and this tends to override some of the rivalry and pursuit of personal interests in which politicians at the state level seem to engage.

On the surface it appears that state officials struggle for higher stakes—larger numbers—more people and more money. This is balanced on the local level by the fact that many issues are more direct, more personal, and therefore more intensely meaningful. For example, my own primary purpose in seeking election to the school committee was to try to improve the quality and effectiveness of our school system. My aim was (and is) motivated by my desire to provide the best possible educational environment for my children. This approach involves attempting to improve the opportunities available for all of the children in the town.

My interest in my fellow townspeople and their children has increased with time and with my service in public office. In addition, I have developed an increased sense of loyalty to the town as a whole. At times the work is stressful, with occasional public confrontations that can become quite intense. The work requires a great amount of time and study, much of which is devoted to contract negotiations and the development of budgets.

This public service is rewarding in many ways—intellectual stimulation in such fields as education, law, government, and finance and the satisfaction that comes with the accomplishment of something that one values. A special source of interest and satisfaction that it offers is the opportunity to apply my psychiatric and psychoanalytic training, experience, and skills to the field of elective politics. It can also offer opportunities for creativity, innovation, public attention, power, and influence.

PUBLIC SERVICE ORIENTATION

It is my impression that the politicians whom I have observed and with whom I have interacted are more dedicated, less selfish, and more consistently directed

toward the benefit of their constituents than are the politicians described by Greenblatt. I suspect that an actual difference exists even after taking into account possible bias by either or both observers and ambiguities of descriptive terms. This impression should be tested by the experience of other observers.

The difference, if it exists, may be based on less conflict between personal and constituents' interests on the local level. A politician's public service orientation (altruism) may be enhanced by or be in conflict with his personal adaptive needs (egoism). His political actions result from the influence of both the public and personal factors. If his career or livelihood is threatened, the politician is more likely to place his personal interests above the public benefit. Like most of my fellow politicians, I derive my income from sources other than the town treasury. This allows me the freedom to support, when necessary, issues that may be unpopular without having to worry about my family's financial security.

Most state and federal politicians start at the local level. Numerous factors of personality or life circumstances influence the local politician's decision to try to move on to the state level. For example, it has been suggested to me that I run for county commissioner or state representative. These positions do not appeal to me because they would drastically limit the time I could devote to psychiatry. More important, my children are still in school and much remains to be accomplished in terms of the quality of education in the local school system.

For someone who wants to make a career in politics, election to state office usually represents advancement. It also permits considerable latitude for political action away from the scrutiny of the electorate, especially in the intervals between election campaigns. Much can be obscured by the intricacies of legislative committee action and by the complexities of legislative parliamentary maneuvering. These shields are less available to the local official; thus self-indulgent behavior is more readily exposed and reproached.

A factor that exerts a strong influence on an elected official's public service orientation is his relationship with his constituents. This is an area that I have been privileged to observe from the inside. Some of my fellow politicians confide in me from time to time, and I can observe my own subjective experiences. In this process my psychoanalytic and psychotherapeutic experience has proven to be superbly useful.

The elected official's relationship with his constituents can be highly complex and variable. It can include fear, resentment, loyalty, affection, contempt, and envy—many of the emotions that human beings can feel toward one another. The elected official's feelings and their associated attitudes and impulses can fluctuate and vary with time. They are influenced by factors introduced by the constituents, the situation, and the politician himself.

The politician's relationship with the electorate at both the state and local levels is analogous to, and possibly more complicated and varied than, a physician's relationship with his patient (1). It contains transference and nontransference elements (7), countertransference and noncountertransference elements (8), and a profusion of situational factors.

It is this subject area that provides a particularly rich domain of study for the psychiatrist in elective office. Its exploration is beyond the scope of this article, but a basic hypothesis should be stated here. The elected official at any level of government, who is particularly vulnerable to the analog of countertransference reactions (1), may carry into his work some highly inappropriate and unconsciously determined impulses and actions. To what extent these might contribute to Greenblatt's "political jungle" remains to be discovered.

The B-Mitten EEG Pattern and Tardive Dyskinesia: A Possible Association

BY JAMES T. WEGNER, M.A., FREDERICK A. STRUVE, PH.D., AND JOHN M. KANE, M.D.

Tardive dyskinesia is a well-recognized complication of neuroleptic drug treatment (1). The different syndrome definitions, patient populations, and examining techniques that have been used preclude accurate prevalence determination, but estimates suggest that 3–6% of patients in mental hospitals and approximately 20% of elderly chronically institutionalized patients exhibit tardive dyskinesia related to neuroleptic drugs (2). Estimates of prevalence among long-term psychiatric patients range from 2.2% to 56% (3). Although numerous pharmacological approaches have been used, an established treatment for tardive dyskinesia has not emerged and efforts directed toward prevention are of enormous importance (4).

Factors potentially predisposing to tardive dyskinesia have been discussed previously (1). Most reported cases have been in schizophrenics, probably because such patients are exposed to neuroleptics over long periods of time. However, tardive dyskinesia also occurs in other patients who receive neuroleptic treatment, including those with affective illness, psychoneuroses, chronic pain syndromes, or personality disorders. Although prospective studies are lacking, there is no evidence that tardive dyskinesia occurs more often in patients previously manifesting acute drug-induced dyskinesias. One report (5) suggested that tardive dyskinesia occurs more often in patients who previously experienced drug-induced parkinsonism, but this may reflect exposure to higher doses of antipsychotic drugs. The association of tardive dyskinesia with preceding organic brain damage, ECT, frontal leukotomy, advanced age, female sex, and antiparkinsonian agents has been suggested, but substantiating epidemiological data are lacking.

Paulson (6) reported EEG findings in 30 patients (mean age=57 years; range, 34–80) with tardive dyskinesia resulting from neuroleptics. The EEGs were obtained after tardive dyskinesia was diagnosed. Seven patients had either diffuse or focal slowing, 4 had paroxysmal epileptiform bursts, and 19 were normal—although in 11 of these 19 the voltage averaged less than 20 microvolts. There was no matched control group without tardive dyskinesia in the study, and some of the EEG results (i.e., slowing) may reflect a somewhat higher incidence in older subjects in general. Gardos and associates (7) reported that abnormal EEG was one of five variables contributing to a discriminant function analysis that significantly identified tardive dyskinesia subjects. However, subanalysis of relative incidence of EEG abnormality in patients with and without tardive dyskinesia failed to reach significance. The types of EEG abnormality were not specified.

Subjects and Method

This report suggests an unusually high incidence of the B-mitten EEG dysrhythmia in patients with tardive dyskinesia. Twenty patients who had waking and sleeping EEG tracings were identified. The sample consisted of 13 male and 7 female patients with a mean age of 29.8 years (range, 16–66). The diagnoses included schizophrenia, N=17; bipolar affective illness, N=2; and unipolar manic depression, N=1. The mean total time of exposure to neuroleptic medication was 2.64 years (range, 6 months–5 years), and the

The authors are with the Department of Psychiatry, Long Island Jewish-Hillside Medical Center, Glen Oaks, N.Y. 11004, where Mr. Wegner is Research Psychometrician, Dr. Struve is Director, Clinical-Research EEG Laboratory, and Dr. Kane is Acting Director of Research. Address reprint requests to Dr. Kane.

The authors wish to thank Frederic Quitkin, M.D., and Arthur Rifkin, M.D., of the Department of Psychiatry, College of Physicians and Surgeons, Columbia University, and the New York State Psychiatric Institute, for their assistance in diagnosing tardive dyskinesia.

TABLE 1

mean highest dose of neuroleptic medication (in chlorpromazine equivalent) was 1006.1 mg (range, 100–2500 mg). The medications were as follows: chlorpromazine, N=9; fluphenazine, N=6; thioridazine, N=3; perphenazine, N=1; haloperidol, N=1.

Results

Table 1 shows the B-mitten EEG findings cross-tabulated with adequacy of sleep depth for B-mitten detection. Of the 9 patients who had inadequate sleep level for mitten detection, 4 showed EEG abnormalities other than the B-mitten pattern. While 70% of the tardive dyskinesia patients had some positive EEG finding, the most striking feature of these data is the exceedingly high incidence of the B-mitten pattern. It must be stressed that the mitten pattern can *only* be detected in moderately deep and deep sleep EEG recording (stages III and IV). Mittens cannot be seen while the subject is awake, drowsy, or in light spindle sleep. Overall, 50% of the tardive dyskinesia patients displayed mittens; of the 10 patients without this EEG finding, 9 had EEGs without sufficient sleep depth and are thus potentially "false negatives" concerning the mitten signal. When the mitten incidence is corrected for sleep adequacy, it is seen that of the patients with adequate deep sleep, 90.9% displayed the mitten pattern.

For 3 patients, mittens were recorded at least 12 months before the onset of tardive dyskinesia and for 2 others the mitten signal was recorded after tardive dyskinesia was diagnosed but at a time when tardive dyskinesia symptoms had reversed and were no longer present. Five patients had symptoms of tardive dyskinesia at the time mittens were recorded. It is possible but not likely that B-mittens are merely a concomitant physiological sign of symptomatic tardive dyskinesia.

Discussion

The B-mitten pattern was originally described by Gibbs and associates (8). A condensed review and complete reference list for this pattern has been provided by Struve and Klein (9). In summary, B-mittens are rare among normal controls and general medical referrals (i.e., those without psychiatric complaint) and occur almost exclusively within psychiatric populations. Mittens are only recorded during deep sleep and are seen best in monopolar recordings where the pattern occurs symmetrically over the bilateral frontal or frontoparietal areas. Several lines of evidence, including tumor studies (10), converge to suggest that B-mittens are subcortical in origin. Recent studies by Struve and Klein (9) have provided evidence that this dysrhythmia may have a highly significant association with symptoms of affective dysregulation (primarily dysphoric) that cuts across broad diagnostic categories.

If our preliminary findings are confirmed, this EEG pattern could be used to identify patients at high risk for tardive dyskinesia, and prophylatic efforts could be made early in treatment. Why mittens may relate to tardive dyskinesia is obscure, and the role, if any, that mittens play in the pathophysiology of this condition is unknown. It is intriguing to speculate that the subcortical mitten dysrhythmia may signal a vulnerability to dopaminergic dysregulation within nigrostriatal pathways—perhaps potentiating dopamine receptor hypersensitivity secondary to prolonged neuroleptic blockade. The association of the mitten pattern with affective dysregulation may also suggest that patients with affective symptoms are more susceptible to tardive dyskinesia. The fact that different biogenic amine system abnormalities are putatively involved in affective illness (norepinephrine and serotonin) and schizophrenia (dopamine) could suggest different susceptibilities to the development of tardive dyskinesia. However, mitten pattern-neuroleptic interactions in tardive dyskinesia development are likely to be complex and our understanding of such relationships confined to mere speculation for a considerable time.

Currently, we are selecting a control group of patients who do not have tardive dyskinesia with deep sleep EEGs to be matched with tardive dyskinesia patients on a number of relevant variables. Furthermore, a prospective study, which is presently being planned, will further clarify the potential of the B-mitten patterns for predicting patients at high risk for tardive dyskinesia.

Rapidly Recurring Seizures of Psychogenic Origin

BY KUTTIKATT P. POULOSE, M.D., F.R.C.P. (C), AND ARTHUR A. SHAW, PH.D.

Seizure of psychogenic origin is a well-recognized entity. However, repeated "seizures" that outwardly simulate status epilepticus are rare. It is important to recognize these cases in order to avoid administration of unnecessary and large doses of anticonvulsant medications with their attendant risks. A case we recently confronted illustrates some of the problems in the recognition and management of this uncommon problem.

Case Report

Mr. A, a 50-year-old man, was transferred from the psychiatry service to the neurology ward on July 14, 1975, for control of "seizures." He had a background of "seizures" over a period of 20 years for which he receives disability compensation and was under treatment with diphenylhydantoin, 100 mg t.i.d., and phenobarbital, 30 mg t.i.d. Mr. A also had multiple hospitalizations for excessive drinking. His seizures were characterized by staring, followed by a cry and stiffening of the whole body, sometimes with arching forward but not followed by a clonic phase. He appeared quite clear headed soon after the seizures, even after repeated episodes, and would joke with nursing personnel. He had about 50 seizures each day in rapid succession. During some attacks he threw himself off his bed but was not hurt. He often expressed concern for the demands in time and effort his condition caused the nursing personnel and physicians.

A skull series and brain scan were normal, as were blood count, BUN, creatinine, total proteins, and electrolytes. Chest X ray revealed no abnormalities. Random blood glucose was 230 (he was on I.V. dextrose). An EEG done on two occasions when he was seizure-free for brief periods showed no abnormalities, as did an EEG recorded while the patient was in a "seizure" episode. ECG was normal.

He was treated with I.V. diazepam, I.M. phenobarbitone, and paraldehyde during his first 3 days of hospitalization. His seizures continued in spite of these medications. He was also placed on small liquid feedings between seizure episodes. On the fourth day the patient insisted on solid food. He was told that with frequent seizures, introduction of solid food can result in aspiration and therefore he could be given solid food only after his seizures ceased. The seizures promptly subsided and he was seizure-free thereafter until his discharge from the hospital 10 days later at his own request. An evaluation by the psychology service reinforced the impression that the patient had characterological problems (manipulative). The psychologist's impression was that the seizures were less likely to be hysterical than consciously controlled.

Discussion

The dramatic presentation of this case, with repeated uncontrolled seizures, led us initially to consider status epilepticus. However, several aspects of this case contraindicated the diagnosis of a true seizure disorder. Epilepsy is characterized by intense cerebral neuronal activity followed by postictal metabolic cerebral depression of varying degrees and duration (1). Postictal mental cloudiness is commonly observed with grand mal seizures, particularly when the seizures occur in rapid succession, when patients are often comatose following the seizure episode (2). The mental clarity of our patient and his jocularity between seizure episodes would have been impossible to explain had these episodes been true seizures. The three EEGs recorded during his hospitalization, one during an episode of "seizure" activity, showed no abnormalities. Although not definitive, this is a strong argument against a diagnosis of true seizures.

Although the EEG may help in differentiating true epileptic seizure from hysterical seizures, it is unfortunately true that epileptic attacks may occur without evident changes in the scalp recording. This situation is frequently seen in Jacksonian epilepsy, where one presumes that the focus is so discrete and the discharge of such low amplitude that it fails to be conducted to the surface electrodes (3). This patient's desire to have a regular diet was so intense that the suggestion of regular diet as a reward for cessation of seizures was effective. The question of conversion reaction versus a conscious process is relevant in this

case, but the two etiologies have much in common. The difference is largely one of the relative degree to which consciousness participates in the reaction. Discrepancies, contradictions, and exaggerations of symptoms are more frequent in malingering. The malingerer commonly expresses much concern about his symptoms, and results of the Minnesota Multiphasic Personality Inventory may suggest a tendency toward lying and deception. In conversion hysteria, patients manifest little concern about their symptoms. In cases of malingering, surprise examination may unmask the deception. Conscious and unconscious factors are interwoven in malingering (4).

This case illustrates the point that uncritical acceptance of previously documented "seizure disorder" may help mask its true nature.

Mother-Son Folie à Deux: A Case of Attempted Patricide

BY LANDRUM S. TUCKER, JR., M.D., AND THOMAS P. CORNWALL, M.D.

Since it was first labeled by Lasegue and Falret (1) 100 years ago, folie à deux has been a rare and interesting phenomenon. Gralnick (2) stressed the importance of folie à deux in understanding psychoses and interpersonal relationships. Greenberg (3) summarized data on the antisocial sequelae of such relationships—crimes committed by a folie à deux pair. In relation to this, Pulver and Brunt (4) speculated on the handling of hostility by projection in cases of folie à deux. The following case report describes a crime committed by a mother and son.

Case Report

Bobby A is a 10-year-old boy who was admitted to a juvenile psychiatric unit after he had been detained for allegedly burning down his father's house.

Two years before this admission, Bobby's parents had been divorced after a stormy marriage of 18 years. Ms. A's mother had been diagnosed as paranoid schizophrenic and her older brother was felt to be "somewhat strange." She had always felt "very close" to her mother. Her father was a "hard-working" man who was away from home often, including an absence of several years during Ms. A's adolescence when he was out of the country on a "business assignment." During that time he became extremely ill and almost died. Ms. A remembers many fantasies of becoming a doctor at that time.

When Bobby was born, Ms. A felt "abandoned" by her husband because he was away on business just as her father had been. She was depressed for some time after Bobby was born. Bobby was a healthy child, met all developmental milestones normally, and did well during his early grade school years. When Bobby was 8 his parents separated and divorced, and he and his mother moved to a town near by.

Six months prior to admission Ms. A and Bobby moved to the west coast, where they lived in various cities for short periods and kept to themselves. She began to tell Bobby that his father wanted to kill them. She started staying up all night with Bobby, telling him that Mr. A had put razor blades in their beds, cut her hair, and poisoned their pets. Bobby did not believe his mother at first since he knew his father was living across the country, but he was afraid to disagree for fear that his mother might hurt him. Slowly Bobby began to feel his mother was right and they began to plot to murder Mr. A. They decided to burn down his home while he slept. After several months of planning, Bobby flew alone across the country to his father's hometown and set his father's house ablaze that night. Mr. A barely escaped in his night clothes and Bobby was found by the police walking away from the flames. Ms. A returned to the state and was placed in a mental institution.

When Bobby was seen initially he was very anxious, with poor eye contact and loose associations. His initial themes in therapy centered around a drawing he did of a spaceship heading toward a large sun. From

The authors wish to thank Florence H. Copland, M.S.W., for her collaboration in the evaluation of the case reported.

the ship came a cord that attached to a smaller ship. Bobby said the smaller ship went ahead of the big ship to check things out. He was concerned that the big ship's outer shell was melting away. The mission of these ships was to destroy the sun, but they were being destroyed. Bobby wished the ship could get back to earth safely.

In addition to individual therapy Bobby was treated by therapeutic milieu, including school and recreation. One especially important factor in his treatment, a point that has been stressed before (5), was separation from his mother. On the ward Bobby was initially overcontrolled, polite, and bright (his IQ was 112). In the first few weeks he was inadvertently allowed to receive two letters from his mother, and at those times he again manifested severe anxiety, poor eye contact, and loose associations.

After 2 months the themes in Bobby's play began to change. He began recurrent battles using a giant soldier from outer space who came with a flame thrower to destroy a "special" house full of smaller soldiers. He began to talk directly of his fear of his mother and his disbelief that he could have had the "crazy" thoughts about his father being so bad. At this time his thoughts were organized and he was relaxed and more open with his feelings.

At the end of 3 months, Bobby had shown no overt psychosis for several weeks and so, after careful consideration, he was sent home to his father. His father had worked closely with us, including participation in once weekly individual therapy. Themes in the 9 months of Bobby's outpatient therapy since discharge have moved from the earlier battles to playing checkers and talking about school and activities. Bobby also has begun writing songs. His first one said, "I'm lonely since I left you—but I've got my feet back on the ground."

Bobby is doing above average work in school, participates in sports, has made friends, and gets along well with his father. His mother remains hospitalized.

Discussion

Past efforts at explaining criminal activities involving a folie à deux situation have focused on 1) interpersonal regulation of hostility by projection, and 2) imposing of delusions by a psychotic, more intelligent, dominant partner on a less intelligent, passive partner who identifies with the dominant one. Certainly, some of this is evident here. Another factor in his case is a "fit" in the dominant and passive partners' unconscious motivations—the wish to kill the father figure in order to possess the mother. Bobby wished to destroy his father to win an oedipal victory (possession of his mother), while Ms. A., so strongly attached to her mother psychologically, wished to destroy her father symbolically to gain a negative oedipal victory (6). In the regression to psychosis both acted on their unconscious oedipal wish to destroy the father figure, while the conscious delusion was that he wanted to destroy them. Further case studies are needed to determine whether the concept of a "fit" in unconscious wishes can add to our understanding of folie à deux and crimes related to the syndrome.

A Case of Lycanthropy

BY HARVEY A. ROSENSTOCK, M.D., AND KENNETH R. VINCENT, ED.D.

Lycanthropy, a psychosis in which the patient has delusions of being a wild animal (usually a wolf), has been recorded since antiquity. The Book of Daniel describes King Nebuchadnezzar as suffering from depression that deteriorated over a seven-year period into a frank psychosis at which time he imagined himself a wolf. Among the first medical descriptions of lycanthropy were those of Paulus Aegineta during the later days of the Roman Empire (1). In his description of the symptom complex, Aegineta made reference to Greek mythology in which Zeus turned King Lycon of Arcadia into a raging wolf. Thereafter, references to lycanthropy appeared in the ancient literature. Many medieval theologians envisioned lycanthropy as a consequence of the evil eye (2).

Delusions of being a wolf or some other feared ani-

mal are universal and, although rare in the industrialized countries, still occur in China, India, Africa, and Central and South America (3, 4). The animals in the delusional transformation include leopards, lions, elephants, crocodiles, sharks, buffalo, eagles, and serpents (3, 4).

Not infrequently, bizarre and chaotic sexuality is expressed in a primitive way through the lycanthropic symptom complex. Patients whose internal fears exceed their coping mechanisms may externalize them via projection and constitute a serious threat to others. Throughout the ages, such individuals have been feared because of their tendencies to commit bestial acts and were therefore hunted and killed by the populace. Many of these individuals were paranoid schizophrenics (2).

Case Report

A 49-year-old married woman presented on an urgent basis for psychiatric evaluation because of delusions of being a wolf and "feeling like an animal with claws." She suffered from extreme apprehension and felt that she was no longer in control of her own fate; she said, "A voice was coming out of me." Throughout her 20-year marriage she experienced compulsive urges toward bestiality, lesbianism, and adultery.

The patient chronically ruminated and dreamed about wolves. One week before her admission, she acted on these ruminations for the first time. At a family gathering, she disrobed, assumed the female sexual posture of a wolf, and offered herself to her mother. This episode lasted for approximately 20 minutes. The following night, after coitus with her husband, the patient suffered a 2-hour episode, during which time she growled, scratched, and gnawed at the bed. She stated that the devil came into her body and she became an animal. Simultaneously, she experienced auditory hallucinations. There was no drug involvement or alcoholic intoxication.

Hospital course. The patient was treated in a structured inpatient program. She was seen daily for individual psychotherapy and was placed on neuroleptic medication. During the first 3 weeks, she suffered relapses when she said such things as "I am a wolf of the night; I am a wolf woman of the day . . . I have claws, teeth, fangs, hair . . . and anguish is my prey at night . . . the gnashing and snarling of teeth . . . powerless is my cause, I am what I am and will always roam the earth long after death . . . I will continue to search for perfection and salvation."

She would peer into a mirror and become frightened because her eyes looked different: "One is frightened and the other is like the wolf—it was dark, deep, and full of evil, and full of revenge of the other eye. This creature of the dark wanted to kill." During these periods, she felt sexually aroused and tormented. She experienced strong homosexual urges, almost irresistible zoophilic drives, and masturbatory compulsions—culminating in the delusion of a wolflike metamorphosis. She would gaze into the mirror and see "the head of a wolf in place of a face on my own body—just a long-nosed wolf with teeth, groaning, snarling, growling . . . with fangs and claws, calling out 'I am the devil.' " Others around her noticed the unintelligible, animal-like noises she made.

By the fourth week she had stabilized considerably, reporting, "I went and looked into a mirror and the wolf eye was gone." There was only one other short-lived relapse, which responded to reassurance by experienced personnel. With the termination of that episode, which occurred on the night of a full moon, she wrote what she experienced: "I don't intend to give up my search for [what] I lack . . . in my present marriage . . . my search for such a hairy creature. I will haunt the graveyards . . . for a tall, dark man that I intend to find." She was discharged during the ninth week of hospitalization on neuroleptic medication.

Psychological data. On the Wechsler Adult Intelligence Scale, the patient's performance showed normal intellect; the subscale configuration was devoid of behavioral correlates associated with organicity, as was the Bender Motor Gestalt Test. On the Holtzman Ink Blot Technique, the performance was indicative of an acutely psychotic schizophrenic with distorted body image and gross sexual preoccupation The Lovinger Sentence Completion Blank was corroborative. The Minnesota Multiphasic Personality Inventory was interpreted as showing an acute schizophrenic reaction with evidence of obsessional thinking, marked feelings of inferiority, and excessive needs for attention and affection.

Discussion

We believed that the patient suffered from chronic pseudoneurotic schizophrenia. What is of particular interest is that the delusional material was organized about a lycanthropic matrix. Her symptom complex included the following classic symptoms:

1. Delusions of werewolf transformation under extreme stress.
2. Preoccupation with religious phenomenology, including feeling victimized by the evil eye.
3. Reference to obsessive need to frequent graveyards and woods.
4. Primitive expression of aggressive and sexual urges in the form of bestiality.
5. Physiological concomitants of acute anxiety.

These symptoms occurred significantly in the absence of exposure to toxic substances. Furthermore, the patient responded to the treatment protocol used for acute schizophrenic psychosis. After reviewing ancient and modern literature, it is felt that the differential diagnosis for lycanthropy should include consideration of all of the following possibilities: 1) schizophrenia, 2) organic brain syndrome with psychosis, 3) psychotic depressive reaction, 4) hysterical neurosis of the dissociative type, 5) manic-depressive psychosis, and 6) psychomotor epilepsy. The last item is mentioned because of reports that individuals suffering from lycanthropy have been described as being

"prone to epilepsy" and suffering from intercurrent amnestic episodes (3).

A search of modern literature[1] produced three cases. In two cases (4), the patients were ultimately diagnosed as having paranoid schizophrenia, facilitated by involvement with hallucinogenic drugs, and chronic brain syndrome with periodic psychoses. In the third case, described by Morrell in 1852, it seems that the patient suffered from a deteriorating psychotic depression (5).

We believe that the metamorphosis undergone by the patient we have described provided temporary relief from an otherwise consuming sexual conflict that might have taken the form of a completed suicide.

Lycanthropy is a rare phenomenon, but it does exist. It should be regarded as a symptom complex and not a diagnostic entity. Furthermore, although it may generally be an expression of an underlying schizophrenic condition, at least five other differential diagnotic entities must be considered.

Biofeedback Treatment of Tardive Dyskinesia: Two Case Reports

BY HELEN ALBANESE, M.D., AND KENNETH GAARDER, M.D.

Tardive dyskinesia, a movement disorder associated primarily with neuroleptic therapy, is characterized by constant, stereotyped, involuntary movements of mouth, lips, and tongue, sometimes accompanied by choreiform movements of limbs and trunk. Movements cease during sleep and are more prominent when the patient is anxious. Patients are sometimes able to control the movements voluntarily (1, 2). Biofeedback, in which the patient receives immediate physiological information about his movements, may assist patients to learn symptom control. This hypothesis borrows from the finding that similar movement disorders can in some cases be relieved by biofeedback. Farrar (3) has reported the use of biofeedback to treat orofacial dyskinesias that might represent the same syndrome, and Korein and associates (4) used biofeedback to treat torticollis.

In this paper we will describe the cases of two well-motivated patients with tardive dyskinesia who were given biofeedback training.

Case Reports

Case 1. A 39-year-old stockroom manager with two children had an acute paranoid psychosis a few months after his wife divorced him. He was given trifluoperazine to control his psychotic symptoms and benztropine mesylate to control his pseudoparkinsonian symptoms. Because of his failure to take medication and continued psychotic symptoms, his medication was changed to I.M. fluphenazine decanoate 11 months later. Eight months after the initiation of fluphenazine therapy he developed involuntary chewing movements. The dosage of medication was reduced and the fluphenazine was discontinued after a year. The oral movements improved only slightly. One month after discontinuation of medication, the patient was evaluated for biofeedback training to control the movements. He was free of psychotic symptoms but continued to have almost constant contorting and chewing movements of the mouth, some foot tapping, and slight choreiform movements of the fingers. A baseline psychophysiological profile (5), including EEG, galvanic skin response, frontalis muscle contraction, respiration, and heart beat, showed no physiological evidence of heightened general tension or anxiety. We decided to work directly on masseter muscle movement with electromyogram feedback.

Two bipolar skin electrodes were placed on the long axis of the right masseter muscle. Input from the muscle was fed to an electronic apparatus which then gave three types of feedback to the patient: 1) a sound, with pitch that increased with increasing tension of the muscle, 2) a threshold-controlled beep-like sound signaling the same input, and 3) visual feedback via a meter in front of the patient. The patient was instructed to

The authors are with the University of Texas Health Science Center at San Antonio, 7703 Floyd Curl Dr., San Antonio, Tex. 78284, and Bexar County Teaching Hospital, where Dr. Albanese is a third-year psychiatric resident and Dr. Gaarder is Professor, Department of Psychiatry, and Director, Clinical Psychophysiology Laboratories; the authors are also with the Audie L. Murphy Memorial Veterans Hospital.

The authors wish to thank John Gormly, Penelope Montgomery, and Richard Sherman for their assistance at various stages of this work.

eliminate the beep-like sound, to diminish the sound pitch level, and lower the meter reading. He was encouraged to become aware of sensation in the muscle when he was successful in recapturing this feeling at home. Sessions were held in the laboratory for 45 minutes once a week. Within 3 weeks the patient was able to eliminate movements of the mouth for 15 minutes during the laboratory session. By the 7th session he was able to complete the entire 45-minute session without moving his mouth, and he also had noted marked diminution of mouth movements at home. Movements of feet and fingers decreased markedly also. The 9th session was held after a 2-week interval and the 10th session after a 3-week interval. The patient was totally without dyskinetic symptoms 3 months later.

Case 2. A 51-year-old married farmer, the father of five children, had had several episodes of psychotic depressive illness as an adult. For his last episode, he received antidepressant medication and I.M. fluphenazine decanoate. He developed pseudoparkinsonism immediately, and tardive dyskinesia appeared 3 months after fluphenazine was started. The fluphenazine was discontinued immediately upon the appearance of the dyskinesia, but there was no improvement after a month. At this point the patient was evaluated for biofeedback training.

When we saw him, the patient exhibited constant, severe chewing movements and rhythmic protrusion of the tongue. There were no movements of the extremities. His psychophysiological profile showed physiological signs of tension. Direct work with the right masseter muscle was undertaken, and the patient was trained for 45 minutes once a week with the biofeedback system described above. By the 3rd session he was able to hold his mouth still for 7 minutes in the laboratory. By the 7th session he was movement-free for 20 minutes in the laboratory and reported diminished movements at home. During the 9th session, the only abnormal movement was of the tongue within the closed mouth. At this point his wife became ill and the family moved out of town. No follow-up data are available.

Discussion

The two patients described were both intelligent people who experienced social embarrassment because of severe mouth movements. The first patient had the movements for 5 months before biofeedback training; the second had the movements for only 1 month. Both had been off medication for 1 month without change in movements and improved markedly by the 3rd session of the biofeedback training. A characteristic of tardive dyskinesia is that voluntary quieting of movement in one part of the body often results in shifting of movement to another part of the body. This did not occur in either patient, despite the already existing foot and finger movements in the first patient described. A general reduction of tension was experienced by both patients, and both gave reports of increased well being.

Since spontaneous remission occurs in tardive dyskinesia, it cannot be proven that the biofeedback treatment was responsible for the marked improvement of these two patients. However, the improvement was first noted within training sessions and increased progressively with training, later extending to periods outside the training sessions. Also, in each instance there had been no noticeable improvement before treatment began. We believe this observation warrants further investigation of the treatment approach, and we hope that this report will stimulate others to try similar methods.

The State Hospital: Facility of Last Resort

BY H. RICHARD LAMB, M.D.

The future of state hospitals has been the subject of continuing debate: Should they be phased out and, if so, how (1)? Are they in fact being phased out (2)? What alternative or additional functions should they assume (3, 4)? The California experience is instructive, for there have been unforeseen, although in retrospect not surprising, effects on the state hospitals as the result of attempts to reduce their use. In recent years there have been intensive efforts to explore and exhaust every local alternative before sending any patient to the state hospital. This has been due largely to a combination of pressure and financial inducements from the California state government (5).

Method

In a previous study (6), a sample of long-term psychiatrically disabled patients in the community was defined by the following criteria: functional psychotic diagnosis, 18–64 years of age, on Supplemental Security Income (SSI) for at least 18 months, and residence in San Mateo County (total population 550,000). It was found that the total group of such patients (488) contributed only 20 patients (8%) of the 264 San Mateo County residents who had been sent to the state hospital over a 2-year period ending March 31, 1975. (The figure 264 is an unduplicated count—the total number of admissions during this period was 421 as indicated in data provided by the county mental health services.) This seemed a remarkably small percentage considering the severity and duration of illness of this sample. If not this sample, then who was going to the state hospital? This question led to a decision to review the records of all persons 18 years of age or older sent to the state hospital from San Mateo County during the last months of the study period (December 1, 1974, to March 31, 1975).

Results

In the survey of persons sent to the state hospital there was a total of 92 persons (unduplicated count) during a 4-month period. Of these, 20 were out-of-county residents who, in most cases, were sent to the state hospital rather than a local hospital because the county did not want to pay for the hospitalization of nonresidents. These 20 were dropped from the sample, giving us a sample of 72 San Mateo County residents sent to the state hospital.

Dr. Lamb is Associate Professor, Department of Psychiatry, University of Southern California School of Medicine, 1934 Hospital Place, Los Angeles, Calif. 90033.

TABLE 1
Recent History of Physical Violence

Physical Violence	Men		Women	
	Number	Percent	Number	Percent
In community	28	82	3	33
In local facility	6	18	6	67
Total*	34		9	

*Significantly different, $p<.01$.

Twice as many men as women were sent to the state hospital during the 4-month period studied. Median ages were 24.5 years for men (range, 18–47) and 33 years for women (range, 19–64). It should be noted that the oldest individual in the sample was 64. Most noteworthy is the fact that 77% of the men were under 30 compared with only 29% of the women.

A recent history of physical violence (within the past 2 years) in the community was reported in 43% of the sample. An additional 17% were described as being physically out of control and unmanageable by the local facility that transferred them to the state hospital. Thus issues of violence and control involved 60% of the sample; a higher proportion of the men were in this group (71% versus 37.5%). Table 1 reveals that over four-fifths of the men with a recent history of physical violence had been violent in the community before being evaluated at a local facility, as opposed to only one-third of the women.

Discussion

In California it is required that local (county) mental health facilities screen all persons for whom hospitalization may be necessary and treat them locally if possible. Under these circumstances, who goes to the state hospital? Our study of state hospitals admissions indicated that twice as many men as women are being sent to the state hospital. Almost three-fourths of these men are characterized by a history of physical violence and/or a feeling on the part of local facilities that they cannot control them. The same is true, although to a much lesser extent, of the women. We have also seen that three-fourths of the men are under 30 years of age. Our results (table 1) further suggest that professionals' fantasies and fears of young male patients with a history of physical violence influenced the decision to send them to the state hospital instead of trying to treat them locally.

Our findings, then, show that a major function of the state hospital for a California county of over a half million people is to handle young men who have a history

of physical violence or are thought to be physically out of control, persons with whom local facilities cannot or choose not to deal. (This is not true for the large metropolitan areas of Los Angeles, San Francisco, and Oakland, where large numbers of patients are inadequately screened with regard to their appropriateness for local treatment and are admitted directly to state hospitals.) The result is that as local facilities proliferate state hospital usage shrinks, and dealing with persons who are violent, or thought to be, becomes a primary function of what was once an institution with a wide variety of uses. The state hospital, more than ever, has become a facility of last resort.

Covert Maternal Deprivation and Pathological Sucking Behavior

BY WILLIAM G. SLAUGHTER, M.D., AND CHARLES K. CORDES, M.D.

The varieties of lifelong unhealthy psychological consequences related to inadequate mothering care during the first year of life are well documented (1–5). Prolonged maternal deprivation occurring in an intact family was termed "masked" or covert deprivation by Prugh and Harlow in 1962 (6). Such deprivation can give rise to clinical symptomatology in children that approaches and perhaps equals in severity those syndromes which are usually associated with complete deprivation (separation).

There is now evidence suggesting that some effects of covert maternal deprivation are more immediately apparent than has been previously noted. This report adds to that evidence.

Case Report

George, at the age of 19 weeks, was admitted to the pediatric service of an Army general hospital because of a one-week history of low-grade fever and increasing irritability. His left index finger was found to be "swollen and erythematous with bluish discoloration of the distal tip." There were no other positive physical findings: complete blood count, urinalysis, platelet count, and reticulocyte count were normal, and uric acid was 5.2 mg/100 ml. X rays of the chest and both hands revealed no abnormalities. George had been sucking his index fingers intermittently for several weeks, but his parents had noted that he had started sucking longer and harder. Two days after admission, George was discharged with a diagnosis of "traumatic necrosis of the left index fingertip, secondary to self-mutilation." The parents were instructed to use elbow restraints whenever he was not closely attended, and he was scheduled for outpatient follow-up in the pediatric clinic.

One week after his discharge he was readmitted to the hospital. The left index fingertip was black and necrotic. There was no evidence or history suggestive of physical abuse, and exhaustive laboratory testing revealed no abnormality. Cultures taken from the dry gangrenous area grew out "heavy diphtheroids." George had a course of oral penicillin and was hospitalized for 4 weeks. He was cared for by several members of the ward staff and received a quality of warmth and sustained attention that amounted to multiple mothering. During the course of his four-week hospitalization, there was a gradual but marked decrease in the frequency and intensity of his attempts to suck his index fingers.[1]

George was the product of an unwanted, unplanned pregnancy. His 19-year-old mother was frightened and anxious when she learned she was pregnant. Her marriage to George's 20-year-old father had been arranged hastily. During the pregnancy, she felt alone and helpless. In the 36th week of an otherwise uncomplicated pregnancy, the membranes spontaneously ruptured, and the progress of her labor was such that a cesarean section was performed. She delivered a healthy male child who weighed 3,280 g and was 50.5

Dr. Slaughter is Lieutenant Colonel and Dr. Cordes is Colonel, United States Army Medical Corps. When this work was done, Dr. Slaughter was Senior Fellow in Child Psychiatry, Letterman Army Medical Center, Presidio of San Francisco, Calif., where Dr. Cordes is Chief, Child Psychiatry Service. Dr. Cordes is also Assistant Clinical Professor of Psychiatry, University of California Medical Center, San Francisco, Calif. Dr. Slaughter is now Chief, Community Mental Health Activity, Dwight David Eisenhower Army Medical Center, Fort Gordon, Ga. 30905.

[1]The swelling and inflammation of the proximal portion of the left index finger resolved; the gangrenous tip was allowed to fall off (at age 28 weeks) approximately 1 cm proximal to the nail bed. The stump was functional and clean.

cm in length. Her postoperative course was complicated by pneumonia and a partial wound separation that responded to routine and conservative care. She was discharged 13 days after the cesarean section.

Neither parent felt capable of caring for George when he returned home with his mother. Mother felt depressed, overwhelmed, alone, and helpless in facing what she considered to be an insurmountable and unending task. She did not enjoy caring for her son and felt rejected by him. She spent her waking hours watching television or daydreaming. She never left the apartment unless her husband was with her because she was afraid of being mugged or attacked. The father worked from early morning until late afternoon. He resented and refused his wife's requests that he help care for George. The couple had little money and could not afford recreation. Tension mounted—each spouse felt bitter and cheated by the other. Brief, violent verbal fights followed by long silences were common.

Father reported feeling inadequate to care for his depressed and angry wife, a "screaming baby," and his job. Both parents felt that the doctors had failed to give them adequate instructions in child care or sufficient follow-up care, and they were relieved when George was hospitalized at 19 weeks of age. The admitting pediatrician referred this case to the child psychiatry service after consultation with other services (examinations done on dermatology, neurology, general surgery, and orthopedic services revealed no abnormalities).

Following an evaluation of the family, both parents agreed to begin therapy. Each was seen individually once a week, and George was observed with his mother and/or his father each week. In the course of her therapy, mother was able to make a number of positive shifts and began to feel better about herself, her husband, and her son. She noted that in the past she seldom looked directly at her son and that she now enjoyed watching him and finding that he was also looking at her. Slowly, and much to her surprise, she began to enjoy caring for her son. She liked the weekly visits from a public health nurse and a VISTA couple that had been arranged through consultation with the hospital social work service. She took George with her on walks and visits to newfound friends and spent less and less time watching television and daydreaming. The father was able to be more helpful and began to spend time playing with George while mother prepared meals. As their own anxiety lessened, the verbal fights and prolonged silences ceased. The couple began to enjoy each other's company and to take pleasure in their son's activities. They noted a progressive decrease in attempts to mouth his hands and suck his index fingers. Near the end of the third month of their therapy, George (now 31 weeks of age) was making no effort to suck his fingers. The parents then elected to discontinue their individual therapy sessions.

Comment

A legion of unanswered questions is posed by this case. In the case we have described, one adverse effect of maternal deprivation was reversible with early intervention. The first key to success seems to be early recognition and the second an awareness of the magnitude and importance of parental anxieties. Finally, willingness on the part of the therapist to involve himself or herself with the parents in a therapeutic effort is a concept that requires continued emphasis and evaluation (7).

LETTERS TO THE EDITOR

This section contains reactions to Journal *articles, statements of opinion, comments on Association activities, requests for information, etc. Letters should be submitted in duplicate to the Editor, who makes all decisions regarding publication. Letters must be typed double-spaced throughout and should not contain more than 500 words and 5 pertinent references. Criticisms of published articles will automatically be sent to the author(s) for response. Letters will be edited for clarity and conformance with* Journal *style. We regret that we cannot inform writers of the disposition of letters or return those which are not printed.*

Dopamine Hypersensitivity and Tardive Dyskinesia

SIR: Although "Postsynaptic Supersensitivity in Schizophrenia" by Ghanshyam N. Pandey, Ph.D., and associates (May 1977 issue) was an elegantly conceived and executed study, I must take issue with one of its major conclusions. The authors correctly observed that their data based on the apomorphine-induced growth hormone response did not demonstrate dopamine (DA) receptor hypersensitivity in patients with tardive dyskinesia. However, their implication that DA hypersensitivity is not involved in tardive dyskinesia is misleading. The flaw in their experimental model was the implication that DA neurons and receptors in very distinct areas of the brain are equal in their response to drugs or transmitter. They assayed DA receptor activity in the tuberoinfundibular system, but it is commonly agreed that DA-mediated motor activity arises from the nigrostriatal system. Although there is some evidence (e.g., the Pandey and associates study) that the mesolimbic and tuberoinfundibular systems tend to reflect each other's reaction to drugs, there is good evidence that these systems and the nigrostriatal one do not reflect each other. First, clinical improvement and extrapyramidal symptoms do not correlate well. Second, Smialowska (1), using histofluorescence studies in the paraventricular nucleus of the hypothalamus (PVH) and the caudate putamen (CP), found that spiroperidol, a potent butyrophenone, blocked the enhanced DA fluorescence induced by D-145 (an amantadine derivative) in the PVH but only weakly inhibited the same process in the CP. This result would imply a qualitative difference in DA receptors in the two regions.

Although the authors referred to Retrosen and associates (2) to make the point that there is no increase in DA-sensitive adenylate cyclase activity in the striatum of rats after chronic neuroleptic treatment, this finding in no way means that DA neuron hypersensitivity is not involved with tardive dyskinesia. Burt and associates (3) recently demonstrated that chronic treatment of rats with haloperidol or fluphenazine resulted in a 20–25% increase in DA receptor binding sites assayed with [^{3}H] haloperidol, a phenomenon that does not depend on specific increases in DA-sensitive adenylate cyclase.

In summary, I think that the authors' experimental design was fine for studying the behavioral implications of increased DA receptor sensitivity but was not pertinent in regard to the motor effects of DA neuron or receptor hypersensitivity as seen in tardive dyskinesia.

R. MICHAEL ALLEN, M.D.
Richmond, Va.

Dr. Pandey and Associates Reply

SIR: We were careful to limit our conclusions to the tuberoinfundibular dopaminergic system associated with neuroendocrine response; hence, as Dr. Allen correctly states, one cannot rule out nigrostriatal dopamine supersensitivity from the data, which failed to show an increased growth hormone response following stimulation of DA receptors associated with the tuberoinfundibular system. Neither can one rule out the possibility that the DA receptors associated with the mesolimbic system, and presumably with schizophrenia-like symptoms, display different sensitivities than do the tuberoinfundibular dopamine receptors. It is clearly possible that discrete DA systems in different parts of the brain may have predetermined (by either genetics or environmental influences) differences in sensitivity to DA agonists or may be affected differently by chronic neuroleptic treatment.

Many investigators speculate that there are pharmacologically distinct types of DA receptors in brain. A recent study by Friend and associates (1) suggested that DA receptors may respond to chronic receptor blockade in a tract-specific manner. They report that rats chronically pretreated with haloperidol and subsequently withdrawn show *decreased* [^{3}H] haloperidol binding in the pituitary whereas the binding *increases* in the striatum.

Such differences do not detract from the important finding that neuroendocrine associated DA receptors do not show supersensitivity in tardive dyskinesia as also observed by Ettigi and associates (2), and that neuroendocrine-associated DA receptor activity does appear to distinguish between acute and chronic populations of schizophrenics, as noted in our article.

Explaining Benzodiazepines: Another Approach

SIR: We found the Special Section on benzodiazepines (June 1977 issue) most informative and thought provoking. In a recent issue of *Nature* Squires and Braestrup (1) suggested an additional possible mechanism of action for the benzodiazepines. They demonstrated a high-affinity specific binding of [^{3}H] diazepam to receptors in rat brain, primarily in the frontal and occipital cortex. A total of 21 benzodiazepines were highly selective for the [^{3}H] diazepam binding sites; moreover, several postulated neurotransmitters such as GABA and glycine (or their antagonists) had no inhibitory action on [^{3}H] diazepam binding.

One must not assume immediately that this brain receptor model answers the riddle of the antianxiety effect of the benzodiazepines. Flurazepam, diazepam, and nitrazepam all demonstrated high-specificity binding, while chlordiazepoxide demonstrated approximately 1/30 of this binding potential. The antianxiety effects of both flurazepam and nitrazepam have not been demonstrated (2), so one cannot confidently attribute their receptor binding to an antianxiety effect. If a receptor is hypothesized to be specific for anxiety, then those benzodiazepines with less antianxiety effect should show significantly less binding than the more potent anxiolytics. This is analogous to Synder and associates' phenothiazine model of dopamine receptor binding, which demonstrates that the degree of blockade of the dopamine receptors is well correlated with the antipsychotic effect (3). We also noted a wide discrepancy in binding potential between chlordiazepoxide and diazepam, both well-known anxiolytics. This marked difference should not exist if these sites mediate antianxiety activity. In addition, if the receptor is truly anxiolytic, then other minor tranquilizers (meprobamate, hydroxyzine, phenobarbital) should bind with affinity comparable to the benzodiazepines. The results obtained by Squires and Braestrup tend to negate that hypothesis (1).

Further research is necessary to our understanding of these new receptor sites and their value in delineating the anxiolytic mechanism of the benzodiazepines. We agree with Squires and Braestrup that the search for an "endogenous transmitter substance acting on the benzodiazepine receptor seems worthwhile" (1).

On Residency: Emotions and Spouses' Involvement

SIR: We read "The Emotionally Disturbed Psychiatric Resident" by Andrew T. Russell, M.D., and associates (January 1977 issue) and were particularly interested in the authors' allusion to emotional problems in residents' spouses. We are now collating data for a study that will report results of questionnaires sent to randomly selected directors and spouses of residents. The questionnaires attempted to ascertain spouses' feelings about the residency and to determine whether their involvement on some level would be helpful. The majority of the directors felt that there was either minimal or no involvement of spouses in their programs, but involvement as perceived by spouses themselves was much higher than would have been predicted by the directors' responses. We concluded that directors have surprisingly little knowledge of residents' spouses and their amount of involvement in the residents' training. In light of these findings, Dr. Russell and associates' data pertaining to spouses must be regarded as incomplete because they are based entirely on questionnaires completed by directors.

It was of particular interest that the majority of spouses seemed satisfied with their present level of involvement, which most often included informal discussions at home and attendance at social functions. Specifically, the responses seemed to indicate that increased structured involvement, such as a group, is not desired, even though the residency program puts stress on the marital relationship as well as on the individual resident and his or her spouse.

The conclusion stated by Dr. Russell and associates that "residency programs may need to consider involving spouses in a group experience" is not supported by our data primarily because most spouses and residents do not seem to want such a therapeutic approach to marital stresses, although some spouses were dissatisfied and felt a need for some formal opportunity to resolve their difficulties.

We do not wish to minimize Dr. Russell and associates' concern about spouses but rather to underline the need for individual assessment and constant watchfulness by the directors for signs of marital difficulties, dissatisfaction, or a desire for greater involvement expressed by individual couples. It would seem that approaching the problem on an individual rather than a group basis would be most fruitful.

JUDITH CHUCKROW GOETZL, M.A.
UGO GOETZL, M.D.
Durham, N.C.

SIR: Dr. Russell and associates presented data on emotional disturbance among psychiatric residents based on a survey of residency training directors. We feel that investigative efforts in this difficult field are needed. There has been a reluctance to investigate the prevalence and incidence of psychiatric disturbance among psychiatric residents, perhaps because of a certain understandable defensiveness on the part of psychiatrists.

The low incidence of emotional disturbance in the psychi-

atric residents studied was striking. There is a methodological problem that may account for this in part. Training directors often are not involved in direct continuing contact with residents and may minimize (or maximize) residents' pathology because of a lack of awareness or administrative pressures. Despite documentation of serious disability provided by fellow residents and clinical supervisors, we have observed in a variety of settings a reluctance on the part of administrative faculty to acknowledge manifest illness in psychiatric residents.

We wonder whether a more complete study might include the administration of the survey questionnaire to chief residents, peers, and perhaps outside observers in order to obtain a more accurate data base with regard to the prevalence and incidence of psychiatric disturbance and impaired performance among psychiatric residents. We feel that it is extremely important to have an accurate idea of the scope of the problem in order to deal with it more effectively.

DENNIS P. MILEY, M.D.
BURTON J. CONN, M.D.
San Diego, Calif.

Dr. Russell Replies

SIR: We appreciate these perceptive letters, which raise several important issues concerning our study of the emotionally disturbed psychiatric resident. Both letters point up the major methodological dilemma in research of this kind—who will be the source of information, and how reliable is that source? As we discussed in our paper, we too are concerned about just how much psychiatric training directors know about their residents and how reliable they are in reporting emotional difficulties. But who knows more? At the least, residency directors are directly involved in the selection of residents and reviews of their performance, and they also receive evaluations by supervisors, faculty, etc. As Drs. Miley and Conn point out, chief residents may be a good source of information, but we wonder if there might be similar gaps in their knowledge. Another alternative would be to ask residents to rate themselves and/or their peers. This indeed would provide interesting comparative data but would involve a much larger study with the inherent problem of self-reporting error. However, in spite of these problems we feel a questionnaire study directed to the residents themselves (with strict guarantees of anonymity) would provide very important information.

A combination approach was undertaken by Dr. and Ms. Goetzl, who queried both residency directors and the spouses of residents. We eagerly await their full report. Our data showing a higher incidence of unmarried and divorced residents as well as disturbed spouses among the "problem" residents raise important questions and concerns about marital stresses within a residency training program. Although spouses in an individual program may not desire or require a group experience, it is vital that residency directors be *aware* of the marital stresses and be prepared to offer individual or group help to those spouses who are dissatisfied and feel a need for some formal opportunity to resolve their difficulties.

These letters underline the dearth of adequate information in the important area of the emotionally disturbed psychiatric resident. Further research such as the Goetzls' project is both needed and welcomed. We hope such research will help us anticipate and deal with emotional problems among our residents before they lead to major personal, family, and career disruption.

ANDREW T. RUSSELL, M.D.
Los Angeles, Calif.

A Question of Zeal

SIR: In her letter "Committing Violent Manic Fatients" (June 1977 issue) Frida G. Surawicz, M.D., suggested that an attorney "who took an adversary approach" and succeeded in having his client released from involuntary hospitalization might have violated legal ethics and been guilty of legal malpractice. I disagree. Had the attorney done otherwise, he might have breached an ethical or legal responsibility to his client. In taking an adversary stance—if that is what his client wanted—he merely guaranteed his client's constitutional right to the effective assistance of counsel. Surely, if Dr. Surawicz were in need of legal assistance, she would want no less than the zealous advocacy required of attorneys by the Code of Professional Responsibility.

When a person is faced with involuntary civil commitment, he already has several strikes against him, which can include the prosecuting attorney, his family, his doctor, and often judges (whose deference to psychiatrists is notorious). In the face of all this opposition, it is indecent to deny him the right to a single, zealous spokesman. And when this spokesman prevails against this opposition, does that not say something quite significant about the strength of the case for commitment?

ALAN MEISEL, J.D.
Pittsburgh Pa.

Dr. Surawicz Replies

SIR: Because of space limitations, I was unable to describe the individual cases in detail; presumably, Dr. Meisel has drawn his conclusions from an incomplete data base. In the case he refers to, the patient was brought to our hospital with commitment papers and immediately demanded his release which we refused. He then hired a lawyer, who read his chart and met with us. At the commitment hearing, the judge released the patient from involuntary hospitalization in our facility but decided that he should be transferred to a private hospital for treatment, an option that the patient and his lawyer proposed at the hearing. This seemed to be an excellent solution. Something happens to the patient-doctor relationship when the doctor has to testify in court—moreover, the patient refused treatment. We subsequently learned that the patient and his lawyer did not follow through with the transfer. After a few months, the patient, divorced and broke after some grandiose financial transactions, entered into a severe suicidal depression for which he had to be readmitted to our hospital. I wanted to point out that psychiatrists (hopefully) know more about the treatment of manic-depressive disease and that there is conclusive evidence in the literature that lithium successfully aborts manic episodes and decreases the occurrence of further manic or depressive attacks.

If I suffered from a sickness that seriously affected my judgment and actions, I would prefer to have a lawyer who acknowledged prevailing medical opinion and realized that there can be disastrous consequences from an un-

treated psychiatric illness. Zealous advocacy should not lead to blind identification with a client to the exclusion of objective evidence.

Many of my colleagues feel that we cannot win. To release an untreated and unimproved patient would make us obvious candidates for a malpractice or medical negligence suit by the relatives, or even by the patient himself, for any damages resulting from his illness. The inconvenience of having to attend commitment hearings saved us at least from that fate, but I continue to feel that the moral and ethical responsibility for the patient's well-being was with his zealous lawyer.

FRIDA G. SURAWICZ, M.D.
Lexington, Ky.

Chronology of Combined Neuroleptics and Antiparkinsonian Administration

SIR: It has been reported that antiparkinsonians can decrease significantly the plasma level of neuroleptics (1–5), thus diminishing their therapeutic effects.

We have conducted an investigation to ascertain whether this interaction could be influenced by modifying the chronology of drug administration. The type and dose of neuroleptic and antiparkinsonian medication remained constant throughout the study for a given patient. The population consisted of 19 chronic schizophrenic patients (11 men and 8 women; mean age, 47.9 years; mean duration of illness, 20.2 years). The patients were receiving various neuroleptics (mean daily dose in chlorpromazine equivalents, 768.4 mg) and various antiparkinsonians (mean daily dose in benztropine equivalents, 4.4 mg). During the first 4 weeks, the patients took all drugs at the same time (7:00 a.m., 11:00 a.m., 5:00 p.m.). During the next 8 weeks, the antiparkinsonian medication was given at 7:00 a.m. and 11:00 a.m. and the neuroleptics at 5:00 p.m. and 10:00 p.m. For the last 4 weeks of the study, the medication was again administered on the schedule used during the first 4 weeks. No significant differences occurred throughout the study in plasma levels of neuroleptic (measured weekly), in the psychiatric evaluation (Brief Psychiatric Rating Scale, Clinical Global Impression, and Nurse's Observation Scale for Inpatient Evaluation), and in the intensity of the parkinsonian symptoms. An interval of only several hours between the administration of the neuroleptic and antiparkinsonian medication had no significant influence on the measures used in the study.

These results are concordant with those of another of our studies (5), undertaken simultaneously, in which it was found that after the withdrawal of the antiparkinsonian drug a statistically significant progressive increase of the neuroleptic plasma level lasted 12 weeks before reaching a plateau.

The Life Cycle and Psychiatric Education

SIR: I read with interest the supplement to the *Journal* entitled "American Psychiatric Education: A Review" (March 1977 issue). However, I was struck by the absence of a perspective of the life cycle as a whole, particularly regarding the middle and later years. Training and programs in child psychiatry were mentioned, but adult development and its special crises were not given attention in this review.

Data from the Bureau of the Census (1) indicate that the percentage of the population who are 65 or older has increased substantially to the figure (1976) of approximately 10.39%; projections indicate that this figure will increase to approximately 12.9% by the 1990s. These figures make it abundantly clear that physicians, including psychiatrists and other health providers, must be properly trained with respect to the particular normative features and pathological conditions associated with the middle and later years. As I have indicated on previous occasions, including an overview on "Psychiatry and the Elderly" in the *Journal* (September 1975 issue), psychiatry and other mental health professions have avoided the realities of the changing age structure of our population.

I wish on this occasion again to alert the teachers, leaders, and practitioners of psychiatry to the importance of turning their attention to the perspective of the life cycle as a whole.

ROBERT N. BUTLER, M.D.
Bethesda, Md.

Dr. Eaton Replies

SIR: Dr. Butler's comments concerning the need for psychiatry to give particular attention to the problems of the middle-aged and elderly are most appropriate.

The Psychiatry Education Branch of the National Institute of Mental Health does expect training programs to provide balanced curricula, including the perspective of the life cycle as a continuum of developmental events from birth to death. It is our hope that through increased didactic work and clinical experience in this area, both psychiatric and nonpsychiatric physicians might become better equipped to render appropriate care to people of all ages.

The NIMH Division of Special Mental Health Programs

provides support for discrete training programs in the area of aging, and it is expected that these programs will also lead to improved care for middle-aged and elderly citizens. I thank Dr. Butler for again emphasizing the need for more attention to this increasingly important group of people.

JAMES S. EATON, JR., M.D.
Rockville, Md.

Methodology in a Case Report

SIR: Gregory Asnis, M.D., raised several important questions in his report "Parkinson's Disease, Depression, and ECT: A Review and Case Study" (February 1977 issue). First of all, the case study seemingly provides evidence that ECT was the "active ingredient" in this patient, but no attention is given to the effect of hospitalization in an inpatient psychiatric facility (with its attendant milieu and other modes of treatment) or to exposure of the patients to a study protocol that involves close contact with several physicians on a regular basis. In addition, no mention is made of medications that were given to the patient during his hospitalization. It may well be that these comments do not constitute sufficient grounds to invalidate the report's general premise, but these questions could have been profitably addressed in the discussion; a lack of control over "other" variables is a well-known deficiency of the single-case-report methodology.

Second, the patient's relapse was treated in a manner somewhat inconsistent with the basic hypothesis of the report. Perhaps a course of maintenance ECT should have been used instead of or in addition to the medications that were given. As an extension of my comment above, it would seem that outpatient ECT could serve as a control of sorts for the placebo effect of inpatient treatment. In any event, the single-case-study model would then have been continued in consistent fashion.

In this time of increasing restrictions related to the use of ECT (witness the California experience), it would seem to be incumbent upon us to "tread lightly" in seemingly advocating a treatment that is at once fascinating and controversial. I believe that it would be both useful and advisable to publish articles such as Dr. Asnis' with a discussion, or comments, by the reviewers who have had a role in selecting the paper for publication.

ROBERT A. KUWIK, M.D.
Fort Stewart, Ga.

Dr. Asnis Replies

SIR: The purpose of my report was to isolate the effect of ECT on both depression and Parkinson's disease in a patient with both disorders. Previous reports (1, 2) had commented on the effect of ECT on psychotically depressed patients with Parkinson's disease, noting an alleviation of the symptoms of both illnesses. My article demonstrated that ECT had a specific antiparkinsonian effect even before its antidepressant effect.

Dr. Kuwik suggests that the results are limited because of the case study approach and may be attributable to a placebo effect. It is clear that since my study was based on a single case, the results must be replicated. However, I strongly doubt that these results were due to a placebo effect. Previous studies of treatment in Parkinson's disease have compared L-dopa to placebo in a double-blind within-patient design. Parkinsonian signs deteriorated to pretreatment baseline recordings soon after substitution of placebo and did not improve during weeks of placebo trial, indicating no noticeable placebo effect (3, 4). The extent of improvement in parkinsonism in this single case study argues against a placebo effect. On three rating scales measuring extrapyramidal symptoms, the improvement ranged from 40 to 66%. This marked improvement is superior to therapy with anticholinergics (21%) and comparable to short-term results with L-dopa (53%).

Dr. Kuwik's points regarding medication and follow-up are well-taken. The patient was taken off of all antidepressants and antiparkinsonians for 1½ months before receiving his first ECT. During the hospitalization the only medication he received was an occasional hypnotic for sleep. Shortly after discharge from the hospital (within 7 weeks) the patient's depression and parkinsonism deteriorated to pretreatment levels. Because the patient refused to be treated again with ECT, a neurologist prescribed carbidopa/L-dopa (Sinemet). It might have been informative to treat this patient with ECT to see if his depression and parkinsonism were still responsive to ECT, particularly since his extrapyramidal symptoms responded poorly to the carbidopa/L-dopa (he was placed on this drug 7 weeks post-ECT).

I am thankful to this reader for taking an active interest in my article and I hope that other work will be done to further our understanding of the association between Parkinson's disease and depression and the effects of ECT on these disorders.

GREGORY ASNIS, M.D.
Central Islip, N.Y.

Editor's Note. While exchanges such as those proposed in the last paragraph of Dr. Kuwik's letter might be interesting, they would involve numerous problems. The decision to designate papers as controversial might bring in the possibility of bias. Further, reviewers' comments are confidential. The space required to do what Dr. Kuwik suggests would mean that we would have to decrease the number of articles we publish. We feel that our Letters to the Editor section serves this function well. Also, we do have occasional Opinion and Comment sections for subjects that are generally agreed to be controversial.

Dispensing with "Psychosomatic"

SIR: One is always flattered by having an old book review quoted, even when it is taken out of context and cited as an example of "deplorable ignorance of the current state of the

field." Since Z.J. Lipowski, M.D., chose to do this in "Psychosomatic Medicine in the Seventies: An Overview" (March 1977 issue), I should like to comment briefly on his article.

The essential ambiguity of the term "psychosomatic" was clearly acknowledged in a comprehensive World Health Organization technical report (1), which was not included in Dr. Lipowski's long list of references. Nor did he mention the highly critical conclusions reached by so authoritative an observer as Grinker (2). Special pleading apart, it may reasonably be questioned whether general medicine, clinical epidemiology, and psychophysiology do not now cover the field adequately enough to dispense with the need for so commodious a term as "psychosomatic."

MICHAEL SHEPHERD, D.M.
London, England

Dr. Lipowski Replies

SIR: Prof. Shepherd's only discernible comment on my paper at first glance appears to concern semantics. He contends that the term "psychosomatic" should be dispensed with. This would be a trivial issue, one to be settled by either redefining the term, as I have done, or proposing an alternative one. Prof. Shepherd does neither; instead, he hints vaguely that what the term designates does not need to be differentiated and labeled at all. This, of course, is no longer just a point of semantics but a fundamental issue regarding the validity and usefulness of the psychosomatic concepts. Prof. Shepherd refers to two publications with an implication that they support his contention. In doing so he misleads the readers.

The report of the WHO Expert Committee (his reference 1), chaired by the late Sir Aubrey Lewis, offers a thoughtful and sympathetic discussion of the psychosomatic concept. It points out that the term "psychosomatic" has been used in two senses: 1) to refer to a holistic approach to medical research and practice, and 2) to designate a group of disorders. The report was highly critical of the term "psychosomatic disorders" and stresses that it undermines the unitary approach to medicine and reaffirms the mind-body dichotomy. I fully agree with this and have repeatedly proposed that the term be abandoned. The report pointed out, however, that it is difficult to change firmly established terms and emphasized throughout the value and importance of the psychosomatic approach. It recommended that psychosomatic concepts, research, and training be propagated and extended and suggested how this should be done. Nowhere in the report was it stated that the term "psychosomatic" should be dropped or that what it stands for is invalid and useless. Just the opposite is the case.

Grinker's book was a landmark in the field when it first appeared in 1953. It provided an outspoken critique of the then prevailing trends in psychosomatic theory, especially of Alexander's specificity hypotheses, and helped pave the way for a more critical and scientific phase in the development of psychosomatics. Grinker expressed dissatisfaction with the term "psychosomatic" but neither adopted an alternative one nor claimed that the concepts this term had come to connote were invalid. Again, the contrary is true.

The WHO report urged an "analysis of areas of misinformation and confusion" regarding psychosomatics. To this end I wrote my article and quoted Prof. Shepherd's not-so-old book review as a deplorable example of misinformation. His letter effectively contradicts his complaint that I have quoted him out of context.

Hanover, N.H.

More on Movies

SIR: I was glad to see the article "Images of the Mind" by Irving Schneider, M.D., in the June 1977 issue. I commend him for the excellent parallels he drew between the history of psychiatry and films. I realize the article was not meant to be totally comprehensive, but I would like to make some comments and additions since I have been using commercial films in teaching psychiatry and psychology for the past several years.

Edwin S. Porter made a film in 1905 called "The Kleptomaniac" that dealt with social injustice. The story was of two women, one poor and one rich, both caught shoplifting. The poor one was jailed but the rich one—the kleptomaniac—was freed.

Geriatric psychiatric problems have been competently delineated in three films. "Make Way for Tomorrow" (1937) was a plea for Social Security in which an elderly couple was magnificently portrayed by Victor Moore and Beulah Bondi. It was the first major film to focus on the problems of the aged. A 1966 British film, "The Whisperers," with Dame Edith Evans, depicted loneliness, paranoia, and hallucinations. "I Never Sang for My Father" (1970), in which Melvyn Douglas played an octogenarian, was so well done that it was painful to watch.

The subject of suicide was covered in "14 Hours" (1951), a true story about a man on a ledge in New York City. It depicted reactions of people on the street and also made a feeble attempt at developing some psychodynamics. Martin Gabel had a small role as the psychiatrist and Richard Basehart played the distraught young man. In actuality the man jumped, but the film had a happy Hollywood ending in which he was saved. "The Slender Thread" (1965) dealt with a suicide prevention center; Sidney Poitier kept Anne Bancroft on the phone long enough for a rescue party to arrive.

Producer Val Lewton specialized in psychological horror films, which were well scripted and directed. "The Curse of the Cat People" (1944) was a sequel to his first film, "The Cat People" (1942), which beautifully demonstrated the fantasy playmates of young children and has sometimes been retitled "Amy and Her Friends" and used for teaching purposes. His 1946 "Bedlam" depicted a 1761 London asylum and the inhumane treatment of patients.

The subject of alcoholism in films probably dates back to the first version of "Ten Nights in a Bar Room" in 1903. The great pioneer D.W. Griffith made two one-reelers in 1909: "What Drink Did" and "A Drunkard's Reformation." "The Lost Weekend" (1945) and "Days of Wine and Roses" (1962) are two fine examples of the many talking films on the subject. The drug scene has been covered in such films as "Man with a Golden Arm" (1955), "Synanon" (1965), and "Panic in Needle Park" (1971).

Two outstanding films on schizophrenia were "Life Upside Down" (1965, France) and "Diary of a Schizophrenic Girl" (1970, Italy).

Two crudely made documentaries of interest are "Warrendale" (1966) and "Titticut Follies" (1967). The former dealt with a Canadian treatment center for emotionally disturbed children that encouraged outbreaks of emotion and violence. The latter was filmed at Bridgewater Hospital for the Criminally Insane in Massachusetts and was somewhat sensational and controversial.

There have been many other interesting psychiatric films, such as "The Cobweb" (1955), which depicted administrative battles in a hospital that had a deleterious effect on patients; "Mine Own Executioner" (1948), dealing with a therapist's overinvolvement with his treatment; and "My Six Convicts" (1952), about psychotherapy in a prison setting.

Dr. Schneider has opened the door to a marvelous subject that merits more exploration.

Contractual Agreements with Adolescents?

SIR: In his article "The Ethics of Practice in Adolescent Psychiatry" (April 1977 issue) Derek Miller, M.D., said, "In adolescent psychiatry a contractual system may be antithetical to good treatment because it may imply submission." Generally, freedom to contract implies adulthood and in this respect may be excellent training for the juvenile in learning to accept responsibility for his actions. The contract, far from implying submission, implies equality; if anyone is submitting, it is the psychiatrist who agrees to be equal to his patient, neither dominating nor being dominated. This is not to say that the roles of patient and psychiatrist are interchangeable; they are merely equal in that the therapist offers psychiatric services for which the patient renders a fee.

Legal scholars have noted a movement from a status society, wherein an individual occupies a role that defines him (slave, serf, wife), to a society based on contract, wherein every individual is free to make and break promises and to have consequences flow from these decisions (1). The family is a status social unit in which the individual is a son, daughter, mother, etc. Seen in this context, adolescence is the process of trading in this status for individuality and might very well be the most appropriate time to encourage contracting, with its rights and concomitant responsibilities. Of course this entails a risk for the therapist; a person cannot fire father or mother, but he can discharge a psychiatrist whose services he no longer wants. The therapist who provides high-quality services will have every reason to welcome the opportunity to be accountable.

Another issue in this interesting article is raised by the statement, "It is unethical to betray the privacy needs of young people in treatment; it is also presumably unethical to break the law." It is not unethical to break the law; it is illegal to break the law. Civil disobedience is based on the ability to break the law, but of course the consequences for such a breach may involve a fine or jail sentence.

The California case *In re Lifschutz* (2) involved a psychiatrist who was ethical and spent a brief period in prison because he refused to obey a court order to answer questions and produce records pertaining to a former patient. Dr. Lifschutz maintained in part that the order infringed his right to privacy. The Supreme Court of California disagreed and denied the writ of habeas corpus, stating that not all psychotherapeutic communications are absolutely privileged. Dr. Lifschutz broke the law and paid the price, but he raised the credibility of psychiatrists by his moral and ethical stance.

SUSANNAH SMITH, J.D.
Chicago, Ill.

Dr. Miller Replies

SIR: The benefits of placing the relationship between a minor patient and a psychiatrist on a contractual basis are claimed to include encouraging a sense of adult responsibility and equating the status of the patient and the psychiatrist. Unfortunately, treating disturbed adolescents as if they were capable of being adults does not make this so. Apart from being a dubious psychological approach, the recommendation flouts established legal doctrine. Even nondisturbed minors are generally considered legally incapable of entering into binding contractual relationships (1).

In some states infant incapacity has been removed by statutes, but generally contractual disability is lifted only for "the performance of a medical or surgical procedure, and only for married minors, pregnant minors, or minors of 18 years of age or older" (2). It is difficult to imagine how an adult concept of responsibility for one's actions can be encouraged by having a minor enter into a relationship that he/she can void at any time, even if this approach made psychological sense.

If legal doctrine assumed that a contract for psychiatric service could be considered binding—a concept that would foreclose the minor's option of disaffirmance—a situation would be created that is antithetical to good treatment. It would require the minor to submit on the basis of having come to an agreement that he or she cannot possibly fully understand because of his or her whole psychological makeup.

Psychologically disturbed adolescents have little sense of time, tending to be prisoners of the present, and often gain pathological instinctual gratification from antisocial behavior. This would indicate a significant degree of mental incapacity, and another branch of legal theory refuses to recognize the validity of a contract entered into by individuals so incapacitated.

It would be unethical for a practitioner to set up a contractual relationship without informing a minor of the right to void the contract at any time. However, such information would surely be seen by the minor as an invitation to void the contract. Thus, contractual relationships for minors seem to be both psychologically unreasonable and legally improbable. States that have statutes lifting infant disability for obligations incurred for hospital, medical, and surgical treatment apply only to married minors.

Ethics are rules of conduct recognized in respect to a particular group culture; in this sense it is unethical for psychiatrists to break the law. If ethics are also a set of principles or values relating to the rightness or wrongness of certain actions, the goodness and badness of the motives and ends of

such actions, then it may indeed be necessary for psychiatrists to flout a legal convention.

Consultation: What Settings?

SIR: While Dr. Z.J. Lipowski's expertise in consultation-liaison psychiatry is formidable, his attack on community mental health consultation in "Psychiatric Consultation: Concepts and Controversies" (May 1977 issue) is more polemic than reason. He agrees that psychiatric consultants are needed "in all health care settings," but his definition of a health care setting is restricted to medical agencies and hospitals. Whether we like it or not, a great number of mentally ill individuals are receiving care in a variety of nonmedical settings ranging from self-help groups such as Alcoholics Anonymous, to casework agencies such as Family Service, to alternate service organizations such as the Renewal House in Los Angeles. I fail to see why psychiatrists ought not to offer case or program consultation to these agencies. In addition, school teachers and clergymen are in an excellent position to detect mental illness. I do not believe we should respond only to the cases of mental illness detected by other physicians.

I agree with Dr. Lipowski's contention that consultants should work in areas in which they have been trained. At the University of Missouri, I train psychiatric residents to perform community mental health consultation. At the end of the first year of training, all residents participate in an interdisciplinary 32-hour seminar, which covers such topics as epidemiology, principles of community mental health consultation, community needs assessment and evaluation, racism, rehabilitation, value dilemmas in community mental health, and the importance of social class and cultural variables on mental health. The interdisciplinary makeup of the class is helpful in addressing the problem of role diffusion in community work. Each resident is then assigned to consult with one agency one-half day a week for an entire year. Among the agencies with which residents have consulted are Family Service, the state Mental Health Association, college campus counseling programs, an alcoholism counseling agency, rural outreach offices, and a pastoral counseling training program. In addition to individual supervision, the residents meet as a group for peer supervision. The residents have enjoyed and profited from their consultation work, and the consultees have been satisfied with their services.

Our "unique biological training" does not mean that we should consult only with medical agencies; rather, it provides us with significant knowledge and experience which, in combination with our psychological and sociocultural training, allows us to formulate a more holistic understanding of man and his illnesses and of the many variables that influence the incidence and prevalence of mental illness. The psychiatrist who thinks that his consultation will prevent a war is foolish, but the knowledgeable psychiatrist who consults with school teachers to assist them in dealing with mentally disturbed students and in creating a healthier classroom environment is performing a worthwhile and needed task. Rather than issuing an ex cathedra denunciation of community mental health consultation, Dr. Lipowski's talents might be better directed toward research in evaluating the effectiveness of such consultation.

ARMANDO R. FAVAZZA, M.D., M.P.H.
Columbia, Mo.

Dr. Lipowski Replies

SIR: Dr. Favazza rightly observes that my article is polemical: it expresses controversial views on a contentious subject. Being polemical, however, is neither antithetical to reason nor synonymous with attack or denunciation. I would submit that my paper is none of these things. It contains a reasoned if sharp critique of community mental health consultation, arguing that its scope needs to be restricted while its effectiveness remains to be demonstrated. Others have made similar statements. Garber (1) quoted Cumming as saying, "The literature on (indirect or agency) consultation makes depressing reading for anyone interested in evidence." A review of the most recent literature on the subject concludes that research on the effectiveness of community mental health consultation is conspicuous by its absence (2). Some writers speak of a "crisis in consultation," lament that consultees are indifferent to threats that indirect consultation may be discontinued, and call for accountability in this area (3).

Dr. Favazza does not respond to my specific arguments and proposals but confines himself to challenging his own dramatized and thus distorted version of my article. I have not stated that we should consult *only* with medical facilities but argued that there was documented need for psychiatric consultants in the medical context and that this should influence our priorities. Clearly, some psychiatrists will need to continue providing consultation to nonmedical agencies that help to detect, refer, and rehabilitate mentally ill persons. Surely, psychiatric residents need training in community psychiatry. Their enjoyment of consultation work, however, does not necessarily support its value to the consultees, nor is the satisfaction of the latter evidence of impact on the mental health of the population.

I wrote my article as a contribution to the continuing debate about the proper role and functions of psychiatrists. I have tried to show that one's approach to consultation reflects one's stand on more basic issues regarding the definition of our profession. The outcome of this discussion cannot fail to influence our practice and training, our relations with other health professions, our public posture, and our future as a profession. I hope to have set forth my position unequivocally and supported it with some cogent arguments, facts, and figures. I am persuaded that the role of the psychiatrist needs to be more clearly defined and its limits and limitations made far more explicit. Along with many other colleagues, I believe that psychiatrists will "find it increasingly important to reestablish their medical role" (4). I foresee that in the coming years psychiatry will become more medical and medicine more psychiatric or psychosocial. There are obvious and powerful social, political, and economic forces pushing in this direction (5). This is not to say that we are on the threshold of a psychosomatic millenium! It is important that as we become more medically oriented we do not abandon what is worthwhile in community psychiatry and do not replace the hue and cry of the social reformers with a chorus of opportunistic grasshoppers jumping on the

bandwagon of liaison psychiatry. I suspect that once the heat of the polemic has subsided, Dr. Favazza and I could find more areas of agreement and common purpose than dissent. Evaluation of the goals and effectiveness of our respective work is one such purpose.

Z.J. LIPOWSKI, M.D.
Hanover, N.H.

Criminal Law: Implications for Psychiatry?

SIR: The criminalization of civil commitment procedures over the last decade, recapitulated in a recent article by Stone (1), gives rise to feelings of frustration and impotence in many psychiatrists who feel the emphasis on the patient's civil rights robs him or her of a fundamental right—the right to be restored quickly to a functioning state. It is ironic that during this same period, decisions of the Supreme Court have been nibbling away at many of the due process rights granted by the Warren Court.

Since 1974, the Burger Court has authorized warrantless search of the person of an individual apprehended in the commission of a misdemeanor, sanctioned entrapment by the police as long as "the defendant was predisposed to commit a crime," ruled that police did not violate an individual's privacy or deprive him of his due process rights by circulating his name and picture in a bulletin entitled "Active Shoplifters," even though he had never been convicted of shoplifting, and held that an individual does not have to be advised of his rights according to the *Miranda* decision while being questioned in the police station if he is not technically under arrest. The contradiction between the last mentioned decision and *Lessard v. Schmidt* (2) seems obvious. The former decision says that Fifth Amendment protection does not apply until a formal arrest has taken place; *Lessard v. Schmidt* stated that such protection applies in a medical examination to determine whether commitment is applicable.

Are there implications for psychiatry in these decisions in criminal law? I think there are. Arons and Katsh (3) have suggested that these recent decisions of the Supreme Court are in response to the feelings of an alarmed public that the scales have been tipped too far in favor of the criminal. A similar reaction in regard to the commitment of the mentally ill may be anticipated. Traditionally the community's fear of the "insane" has been greater than its fear of the criminal because of the presumed dangerousness of the former. Ironically, in the present climate, dangerousness is the main justification for involuntary commitment. This fear has been expressed in the reaction of Long Beach, N.Y., to the emptying of the state's mental hospitals. Here in Ohio there is a move afoot to amend the commitment statutes of August 1976 in the direction of modifying some of their more onerous restrictions. Equally significant, families, neighbors, and police are besieging psychiatrists for help in coping with those denied admission under the new laws. Under the pressure of public opinion, a position may eventually emerge that will guarantee adequate protection of patients' rights, balancing that protection against the needs of the community.

During this difficult transitional period, we must not defend nonexistent treatment in some state hospitals or long-term, nonjudicial commitment. We must make our voices heard as clearly as possible, not only in courts and legislatures but in the vital arena of public opinion. We must learn from the abolitionists to speak directly to the public as well as to each other. This period must be used for education about recent advances in treatment and the cost of implementation of the treatment provisions of the new legislation. We may in this way lose some of the battles but win the war.

HENRY L. HARTMAN, M.D.
Toledo, Ohio

Barbiturates and Tardive Dyskinesia

SIR: There has been increasing interest in tardive dyskinesia recently. I have noticed discussions of the use of deanol, and several neurologists with whom I have spoken are beginning to use clonazepam, a benzodiazepine used in the treatment of minor motor and petit mal seizures. I would like to report my experience with a patient whose symptoms of tardive dyskinesia subsided with barbiturate administration.

I have been following the patient, a 55-year-old woman with chronic schizophrenia and extensive state hospital admissions, for about 2 years. During the time I have known her, she has exhibited bland affect, social withdrawal, and at times has frowned constantly. She spoke abruptly, with a poverty of thought, and volunteered little information.

At one point she had been taking thioridazene, 100 mg q.i.d., and after 2–3 months developed slow, continuous sucking and chewing mouth movements. She had no complaints of pain or dental problems. She did complain of fear and uneasiness, and as she spoke of her fears the mouth movements became more prominent.

The thioridazine was discontinued. It was difficult to decide whether her uneasiness and frowning resulted from her basic illness, situational factors, or an extrapyramidal reaction.

Since she had been on numerous antipsychotic medications with no improvement, I placed her on phenobarbital. Before she started taking the phenobarbital, she still had intense abnormal mouth movements 1 week after discontinuation of thioridazene. At this point she was alert, oriented to time, place, and person, and spoke to me in a coherent fashion. She was asked to see a neurologist at one point but failed to keep the appointment.

After 1 week on phenobarbital, 30 mg q.i.d., she was dramatically calmer and was sleeping well. Further, she no longer had abnormal mouth and tongue movements. I have continued prescribing phenobarbital for about 4 months

without phenothiazines and she has remained calm and is still sleeping well. She does not have the abnormal mouth movements unless she fails to take her medication for several days at a time.

I should like to inquire whether other psychiatrists have had positive results with barbiturates and tardive dyskinesia.

LEWIS H. LIPSIUS, M.D.
702 Cherokee St. Extension
Marietta, Ga.

Corrections

The table of contents of the July 1977 issue lists the author of "Fluphenazine Decanoate During Pregnancy" as "M.F. Cleary et al." Dr. Cleary is the sole author.

In the August 1977 issue of the *Journal* (letters to the editor, "Confidentiality: A Solution to the Problem?"), there was an error in the spelling of Dr. Francis J. Durgin's name.

The staff regrets these errors.

BOOK REVIEWS

Style, Character and Language, *by Victor H. Rosen, M.D.; edited by Samuel Atkin, M.D., and Milton E. Jucovy, M.D. New York, N.Y., Jason Aronson, 1977, 388 pp., $15.00.*

This volume contains 14 previously published essays on a wide variety of subjects written by the talented author Victor H. Rosen before his tragic death in 1973. They have been carefully and skillfully edited for posthumous publication. We who value studies in language as one key avenue to understanding the behavior patterns of our patients and their families and our interaction with them in therapeutic endeavors are greatly indebted to the editors. Dr. Rosen was a brave explorer whose writings deserve close study. He opened up many avenues in conventional psychoanalytic thinking to studies by professionals in other disciplines, particularly linguistics, semiotics, linguistic philosophy, cybernetics, thinking, imagination, creativity, and the adaptive functions of language.

The 14 essays are divided into two sections. The first, Language and Psychoanalytic Technique, has 10 chapters with clinical examples of the mutual illumination of basic psychoanalytic assumptions and psycholinguistic theories on such subjects as "Mathematical Thought Process and Abstract Thinking," "Strephosymbolia," "Abstract Thinking and Object Relations," "Schizophrenic Language Disturbance," "Sign Phenomena and Unconscious Meaning," and "Language and Psychoanalysis." It is noteworthy that in the chapter on schizophrenic thinking Dr. Rosen revises considerably Freud's formulation that patients with this psychosis use words as though they were the equivalent of things. Dr. Rosen states,

> According to this revision the psychotic individual does not suffer a "decathexis of things." It is suggested that as a result of regression and withdrawal from social relationships, which both necessitate and facilitate verbal communication, language code connections are disrupted. (p. 169)

The introductory summary by Dr. Atkin, a senior training and supervising psychoanalyst, is a valuable personal critique that helps the reader of Rosen's essays understand the background for them in Rosen's Language Study Group, founded in 1963 at the New York Psychoanalytic Institute, and the group's arduous search for interdisciplinary interaction and enlightenment. This summary is strongly recommended as required reading for all psychothotherapists who believe that language functions are crucial to therapeutic transactions.

The second section of the book has four essays on creativity, talent, the comic, and character style. The introduction to the section by Dr. Jucovy is a splendid biographical review of Rosen's career and his interest in art. The epilogue (pp. 353–360) tells us about the genesis and activities of the Language Study Group and the usefulness of ideas from Charles Morris and Noam Chomsky and their transformations in the group. There is also a chronological list of Rosen's writings.

This collection, although not a textbook, can be highly recommended as a supplement and reference to all students of psychotherapeutic transactions.

HENRY W. BROSIN, M.D.
Tucson, Ariz.

Traité des Hallucinations, Vol. 1 and 2, *by Henri Ey. Paris, France, Masson & Cie, 1973, 1,502 pp., 440 French francs.*

In 1932 Dr. Ey's first paper on the subject of hallucinations appeared in the French periodical *L'Encephale*. Over the following 40 years he persistently pursued the subject, producing some 21 papers and monographs on this topic. Hallucinations and the idea of consciousness have been his two main clinical and research interests. *Traité des Hallucinations* represents a lifetime of effort. It is a more complete and thorough study of hallucinations and delusions than we have in any Western language. The bibliographical wealth alone is enormous; Ey seems to have covered every significant paper or book related to the subject, carefully evaluating this literature from 1950 to 1971.

Traité des Hallucinations is a truly monumental work. Ey's exceptionally felicitous style makes this book a real delight to read. Although not always easily or quickly read, his exposition is a model of the clarity for which the French have so often been congratulated.

On the basis of the fourfold foundation of Janet, Freud, Hughlings Jackson, and Husserl, Ey sets himself the huge task of analyzing what we know about hallucinations and delusions. He also tries to evaluate critically and interpret honestly and unpolemically just what has been learned since 1950. He also goes back to the great classical works of the nineteenth century. It is clear that for many years Ey has been dissatisfied with what he calls the "mechanistic-linear cerebral mythology" and the "myths of the unconscious primary processes." He has applied the insights of Jackson and Sherrington to the architectonics of the CNS and added the rich lore and analytic possibilities inherent in the newer phenomenological philosophy.

Ey freely acknowledges and pays homage to the insights of Freud; Freudian dynamics are integrally incorporated in his thinking and formulations. The result is what Ey chooses to call an organic-dynamic theory of not only hallucinations and delusions but of all psychiatry. The thesis has been worked out, not in the quiet of his study but on the basis of the clinical phenomena nature offers. Forty years of hard clinical experience is at the core of Ey's work.

Dr. Ey gives us a very thorough and critical analysis of the many theories advanced to elucidate the fundamental problem of hallucinations and delusions. Although we have usually considered these to be separate phenomena, Ey views them as closely and inevitably linked: "Hallucinations are

embedded in delusions . . . hallucinations are basically a form of delusion" (p. 829). He demonstrates their essential relatedness.

The author constantly uses four basic ideas in developing his theory and its clinical relevance. The first basic idea is that a hallucination is a pathological phenomenon: "It is a heterogeneous structure, anomic in regard to the infinity of illusions which appear in the normal exercise of our imagination." The second basic thesis consists of considering hallucinatory phenomena, at every one of their levels, irreducible to any elementary and mechanistic theory that would regard the hallucination as a simple result of neurosensory stimulation. The third basic tenet is formulated as an antipsychotogenic thesis of the apparition of hallucinations, which cannot be simply the projection of an affect, even if the affect be unconscious. The hallucination is fundamentally a "negative structure incompatible with the mere force of the wish, or wish fulfillment." The appearance of hallucination requires still another dimension, that of a deficit or breach in the system of reality testing. This antipsychogenic thesis affirms that consciousness is man's defense against the development of hallucinations and delusions. A break in this defense will inevitably result in such phenomena as delusions and hallucinations.

The fourth idea requires for the explanation of the appearance of hallucinations recourse to a hierarchical plan of organization by the psyche. Dr. Ey is very emphatic in his insistence on the fact that a hallucination does not make its appearance on the basis of disorganization of the psychosensorial systems involved. The pathogenesis of hallucinatory phenomena always reveals and betrays the existence of a disorganization of the psychic organism. (It must be noted here that there is no room anywhere in his thinking for body-mind dualism or parallelism.)

Ey rejects the traditional division of hallucinations into the two groups of psychosensorial and psychotic. Rather, he divides them into two large categories: *eidolies hallucinosiques* (which we commonly term "hallucinosis") and delusional hallucinations. These categories inevitably do much to clarify the confusion that usually accompanies discussion about hallucinations.

The chapters on hallucination and cerebral pathology as well as the chapter on hallucinogens are models of clinical description. There is also some very fascinating material on the phenomenology of hallucinations. In the chapter on "Hallucinations in Neurotics" Ey is bitterly critical of the simple, mechanistic-linear theories of the pathogenesis of hallucinations; for the most part his strictures are more than well taken. He carefully dissects the inadequacy of psychodynamic models or theories, not because they lack merit or richness but primarily because, although necessary, they are not sufficient explanations.

It is clear that the author's organic-dynamic model leans heavily on the Jacksonian principle of the dissolution of the superior levels and its inevitable release phenomena, or negative phenomena. Ey refers to hallucinations as "negative structures."

It is difficult in a relatively short review to convey the richness of this massive work and the enormous body of material that the author organizes and presents to the reader. It would indeed be a great pity if this book remained untranslated into English; it is as seminal a work as is Bleuler's monograph on dementia praecox.

JOSEPH ZINKIN, M.D.
New York, N.Y.

Behavioral Intervention: Contemporary Strategies, *by W. Robert Nay. New York, N.Y., Gardner Press (Halsted Press, John Wiley & Sons, distributor), 1976, 370 pp., $19.95.*

This textbook on behavior modification theories and techniques is designed for what the author calls BCA (behavioral change agent) trainees, such as teachers, counselors, and social workers who work with institutional populations. He disparages the disease concept of behavior disorders and prefers to treat them as problems in living that are subject to change by overt conditioning and covert modeling and training.

Nay has enlarged on the earlier, more conventional concept of mechanistic behavior patterns and their modification by stressing the potential for self-direction and demonstrates methods for developing self-control. He calls his system of therapy "phenomenal-behavioral," meaning the use of thoughts, feelings, and sensations (phenomena) as well as extrinsic controls to influence behavior changes.

Although this book is not psychiatrically oriented, it seems to offer some useful suggestions for behavioral management, especially in institutional settings, where there is so often a shortage of personnel and a need for clear-cut and achievable therapeutic goals. There are extensive references and a final chapter on the ethical and legal ramifications of certain types of behavior intervention strategies.

FREDERICK LEMERE, M.D.
Seattle, Wash.

Deinstitutionalization and Institutional Reform, *by R.C. Scheerenberger, Ph.D. Springfield, Ill., Charles C Thomas, 1976, 250 pp., $17.50.*

This book distinguishes itself in one important aspect from many other contributions to the literature on this presently fashionable topic: it is more objective and detached and less emotional. It is not so filled with the slogans and admonishing phrases "to do the right thing" that one unfortunately has to tolerate in the literature on the changes in approach to the problems of the mentally retarded. One may disagree with one or another statement, for example as to the value of litigation versus the damage it does, but at least the book has opinions that can be challenged rather than meaningless phraseology. Fortunately, Scheerenberger keeps his book fairly free from statements of his case in empty phrases when summarizing present trends.

The title may be misleading in one aspect: the material covering deinstitutionalization and the material covering institutional reform are rather unevenly distributed. Presumably following the present swinging of the pendulum away from institutionalization, Scheerenberger devotes the first 186 pages of this 250-page volume to deinstitutionalization and only one 30-page chapter to institutional (residential) reform. I find this regrettable because Scheerenberger is a superintendent of a state institution and could have contributed a great deal more to this subject. When the pendulum swings back to a reasonable use of residential settings when needed, as it already has in some enlightened areas of the country, we shall need all of the constructive thought available to us to improve the institutions.

We have observed the pendulum swing from "everybody should be in a residential setting" to "everybody should be in the community." Gradually, the reasonable, balanced,

and logical approach will prevail; specific indications of individual problems of human beings will be considered. Books such as Scheerenberger's are an asset to this process. His book is recommended to everybody who is interested in the problem of how to find proper living arrangements for mentally retarded people, including the educational, medical, habitational, and other services they need. The reader may not always agree with the specific opinions expressed, but he or she will learn and will be challenged.

BENEDICT NAGLER, M.D.
Lynchburg, Va.

The Psychoanalytic Study of Society 7, *edited by Werner Muensterberger with Aaron H. Esman and L. Bryce Boyer. New Haven, Conn., Yale University Press, 1976, 399 pp., $19.50.*

Although the number 7 on the cover of this book suggests that this is the seventh volume of *The Psychoanalytic Study of Society*, nowhere else is there any information about the preceding volumes and their contents. It is therefore not possible to learn whether there is some kind of overall plan or continuity in the series. Presumably, each volume must stand on its own.

Each of the 12 chapters deals with a different subject. With the exception of the first chapter, "Janusian Thinking and Creativity," which relates exclusively to an individual process, the chapters range over a seemingly diverse field. For example, there is a study of *Peter and the Wolf* as a means of understanding, through music, something of the imagery of the contemporary Soviet man. Other chapters deal with a cross-cultural study of prolonged adolescence and early identification, ghost sickness and superego development in the Kiowa Apache man, the life history and creative psychopathology of a shaman, magic and healing, and the Mackenzie Delta Eskimos. The concluding chapters focus on the origins of Judaism and the Passover Seder.

Although the 11 chapters cover diverse areas, there is a remarkable continuity that is cross-cultural and inclusive of both time and place. The continuity is made possible by the use of a psychoanalytic framework for understanding the phenomena under study. Data are extracted from interviews, observations, and recorded documents and subjected to psychoanalytic scrutiny. What comes through in all of the papers is the remarkable consistency with which people from diverse cultures struggle to control similar primary process functions and impulses and the manner in which diverse cultures exercise social influences in the struggle for control.

The innate destructive impulses that guarantee the dissolution of any society come under the influence of shared unconscious symbolism and consciously shared societal beliefs. It thus becomes possible for a group to live together in some degree of harmony. The powerful ties to the universe in general and to the mother and mother earth in particular give rise to culturally shared superstitions as a means of explaining things. At the same time each individual struggles with questions of sexual identity and the wish to return to the safety of the mother.

These papers make a strong case for a collective unconscious. One reads that oedipal conflicts live out their active existence in the different cultural groups with both regressions to and fixation in pregenital fantasies. Over all hovers the rather desperate yet self-preservative efforts of each culture to bring order and some modicum of harmony through its rituals and institutions. The family stands as the intermediary between the individual and the group in this struggle.

What may seem to the reader to be rather exaggerated interpretations of symbolic thought, feeling, and behavior are nevertheless heard regularly on the couch in the analysis of patients today. Perhaps a brief can be made for a greater use of rituals and ritualized institutions in our society as our mounting scientific understanding of the world in which we live seems to dissolve rather than reinforce controls. Man appears to be incapable of living in groups harmoniously by reason alone.

Having remarked on the sameness of interpretations in the analysis of patients today and the analysis of primitive cultures, I must nevertheless note a degree of unevenness in these papers. The unevenness lies in the fact that in some papers the data are insufficient to warrant some of the extended psychoanalytic formulations. In other papers this documentation is impressive and even sheds light on those in which data are lacking.

The Psychoanalytic Study of Society is not easy reading, but it is illuminating. It gives further credence to my long-held belief that a good psychiatrist can treat any patient, regardless of where the patient is coming from, as long as he or she is aware that all human beings suffer the very same kind of pain but, because of different family and cultural differences, the pain tends to be expressed in different ways.

JAMES MANN, M.D.
Boston, Mass.

Criminality and Psychiatric Disorders, *by Samuel B. Guze, M.D. New York, N.Y., Oxford University Press, 1976, 177 pp., $9.50.*

It is now almost 150 years since Pritchard's formulation of the concept of moral insanity extended the spectrum of mental disorder to include cases variously described as sociopathy, psychopathy, or personality disorder. This opened the doors of the prisons to psychiatry, but it also led to a blurring of the boundaries between psychiatry and criminology, an effect that has been intensified by the further inclusion of alcoholism and drug dependence among the mental conditions. The result has been that although the general public is now willing to see many criminals as mentally disturbed, it has at the same time come to identify all other forms of mental disorder with criminal behavior. This is no more logical than seeing all humans as criminals because all criminals are human. Logic aside, this syllogism has become a reality problem.

A corrective to this trend is badly needed, and *Criminality and Psychiatric Disorders* is a significant contribution in that direction. It reports new scientific data showing that the mental disorders found in prisons are of a different class than those seen in mental hospitals and clinics and that there is little overlap between them. About 85% of the cases of mental disorder in prisons are diagnosed as sociopathy, alcoholism, and/or drug dependence, but the major psychoses and neuroses that make up the bulk of cases in mental hospitals and clinics are seen no more often in prisons than in the general population. A second line of evidence for this point comes from a comparison of behavior after release from a prison or a hospital. Drawing on his own studies, Guze shows that recidivism was involved in a majority of cases

released from prison. The literature, on the other hand, shows that criminal behavior is a relatively rare complication of mental disorders other than sociopathy, alcoholism, and drug dependence.

This book is based primarily on some 15 years of study of almost 300 felons from Missouri prisons. They were interviewed before their discharge and followed up by means of examinations over a period ranging from 3 to 9 years. The interviews were structured, conducted by psychiatrists, and supported by similar interviews with more than 350 first-degree relatives as well as examination of all available records. When direct contact could not be made, information was taken from secondary sources.

The book opens with a broad discussion that reflects Guze's long-standing interest in psychiatric classification and his recognition of its limitations as well as the limitations of statistics on crime. The author provides a definition of terms, a description of procedures, and a general description of the case material; the interview forms are contained in an appendix. The study itself examined the interrelations among such factors as recidivism, mental diagnosis, life history, and various social and demographic characteristics.

Many of the findings tend chiefly to confirm and support existing professional opinion; e.g., the overall high arrest rate after prison release and the correlation between criminal recidivism and youth, previous recidivism, alcohol and drug abuse, sociopathy, and demographic measures of social stress. Some of the findings are new and subject to further confirmation; e.g., the strong evidence that hysteria in women often appears to be the equivalent of sociopathy in men. This formulation is supported by the clinical histories of Guze's index cases and by the incidence of the two conditions among male and female relatives of the felons.

The diagnosis of sociopathy seems to be a stable one, distinct from other forms of psychiatric disorder, rather than a transitional or atypical form of other conditions. Guze briefly mentions a possible organic type, but he does not mention the rather extensive experience with encephalitis lethargica, which in its time showed how damage to the CNS could produce the most lurid cases of sociopathic behavior.

As one becomes interested in a book with extensive presentations of primary data there is always a temptation to pick up the statistical analysis where the author leaves off. Almost always this is a futile undertaking because of errors on the part of the reader and because he or she does not have all the facts (no matter how detailed the presentation the author cannot publish everything). However, the temptation grows stronger the more carefully one reads. For example, it is tantalizing to read that 66 female felons accounted for 15 homicides among their index crimes while 223 male felons accounted for only 11 homicides and 4 attempted homicides. Another puzzle is that only 5% of the men were diagnosed as drug dependent before their index conviction; in the subsequent 9 years of follow-up this figure did not rise spectacularly, even though drug addiction was widely held to be a major cause of crime by that time. Even the figure of 26% of the women seems unimpressive in this context. Another interesting fact is that 15% of the women believed that they had talked to or received messages from God.

Questions of a different type are raised by the finding that among 144 children of women felons, 13 had died by the age of 3 and 6 more were stillborn. Only 9% of the women had been born out of wedlock, and 21% of their pregnancies were not legitimate. As one reads these figures and the data on suicide attempts, mental hospitalization, deaths (violent and otherwise), serious accidents, illnesses, and educational levels, one cannot help wonder what the corresponding figures for the noncorrectional population might be. For the most part this remains a topic for future research.

At the close of the book the author makes a bold suggestion that will undoubtedly raise some eyebrows. He observes that available treatments for sociopathy, alcoholism, and drug dependence are not dependable in most cases (and I think he refers primarily to persons seen in the correctional setting). Further, he notes that conviction for recidivism falls from 60% for ex-prisoners under the age of 40 to 6% for parolees over the age of 40. He concludes that "imprisonment until middle age, at least for recidivist criminals, should result in a major reduction in recidivism after discharge from prison." A discussion of this proposal should be especially interesting and timely in view of the recent moves in the opposite direction, i.e., to declare the prison system bankrupt because of its failures and to deinstitutionalize its population.

The timeliness of this book is further heightened by the recent collapse of the addiction theory of crime in the streets. This explanation of the cause of crime seemed to satisfy the public demand for some sort of causality, but that phase of conventional wisdom has now passed—even though addiction still remains with us. Another explanation must now be found. One can only hope that it will not be another simplistic pancausality like social stress. Guze points out that many other factors must be considered and evaluated and that more research is the only rational approach. Work like that reported in this volume is a good beginning, but all of the studies now in progress seem minuscule in comparison with the magnitude of the problem.

HENRY BRILL, M.D.
Islip, N.Y.

Delinquency and Psychopathology, *by Dorothy Otnow Lewis, M.D., and David A. Balla, Ph.D., with the assistance of Shelley S. Shanok, M.P.H. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1976, 199 pp., $14.75.*

In his brief foreword to this slim volume, Dr. Dennis P. Cantwell says, "This is an important book. It records with precision and clarity a detailed psychiatric study of a group of children referred for evaluation from a juvenile court." In reviewing this book, I can only echo Dr. Cantwell's statement and evaluation. The book is indeed important. In this era of questioning whether the psychiatrist has a role in the juvenile court, a monograph such as this provides a valuable contribution. It details with careful, clear, and logical thinking the important contributions a clinician can make to the understanding and treatment of delinquent children. Most importantly, the authors challenge the pseudoscientific diagnosis of sociopathy.

On the basis of meticulous and careful observation of interviews with delinquent children and their families, the authors identify a group of valid psychiatric diagnoses that truly describe the psychopathology of some delinquent children and their families. Of special importance is their chapter on "Psychomotor Epileptic Symptomatology." After noting a high prevalence of psychomotor epileptic symptoms in a portion of a delinquent population referred for psychiatric evaluation, the authors suggest that these symptoms are probably more common among delinquent children than has previously been recognized and that they should be part of the differential diagnosis of all court-referred children. Obvi-

ously, they should also be a part of the differential diagnosis of all children. If one really believes that a critical mandate of the juvenile court is to treat and rehabilitate children, the treatment implications of this diagnosis are inescapable.

Another clinical observation of the authors is the high prevalence of psychotic symptoms in children and parents referred for evaluation to the court. The treatment implications inherent in these observations may seem obvious to psychiatrists but must be impressed and reimpressed on our legal colleagues who call into question the value and necessity of a psychiatric evaluation of adolescents, asserting that a psychiatric evaluation adds the label of "sick" to the "bad" child.

The authors caution those who are likely to use their findings in the treatment of delinquent children and those who are involved in policy decisions regarding the handling of delinquent children to adhere to the medical admonition, "Above all, do no harm." The authors have followed their own caution and admonish the readers to see this book in its proper perspective, that is, as a beginning study of the relationships between delinquency and psychopathology. If *Delinquency and Psychopathology* serves as a stimulus to future studies, the authors' purposes will indeed be achieved.

ELISSA P. BENEDEK, M.D.
Ann Arbor, Mich.

Malnutrition and Intellectual Development, *edited by John D. Lloyd-Still. Littleton, Mass., Publishing Sciences Group (CHC Corp.), 1976, 186 pp., $12.00.*

The prospect of 100 million malnourished children growing up to become brain-damaged adults, who in turn will parent another deprived, mentally subnormal generation is not altogether science fiction. This significant and well-edited book places current knowledge about the long-range effects of malnutrition on mental development in perspective and shows that nutritional problems require more than nutritional answers. Malnutrition is an important problem not only in underdeveloped countries but also in the United States, where 5% of hospital admissions of children under the age of 2 result from the failure-to-thrive syndrome.

There is no question that severe malnutrition during early life is associated with cerebral atrophy and mental subnormality. Whether the cerebral atrophy is causally related to protein-calorie deficiency, to vascular thrombosis because of dehydration, or to subdural hematomas because of physical abuse is less clear. The accumulated evidence suggests that the longer and more severe the malnutrition during the first 2 years of life, the more serious the effects on intellectual development.

Of special interest is the finding of class differences in malnourished children: language and adaptive behavior were more affected in deprived populations and fine motor function was more impaired in middle-class populations. This class difference highlights the importance of socioeconomic and sociocultural factors in lower-class malnutrition and the likelihood that diets deficient in protein and calories have the greatest impact on the functioning of the cerebellum. All of these effects tend to diminish with increasing age, suggesting that recovery is related to a combination of adequate nutritional replacement and emotional and psychological support. Therefore, efforts to alleviate malnutrition in deprived areas of the world require not only nutritional replacement but emphasis on improvement in the emotional and social well-being of families.

The vulnerability of the CNS during early childhood is highlighted; the critical period for brain development is from early fetal life to the fourth year of postnatal life. Although most neuronal cells are formed in utero, glial cells form primarily during the first and myelin accumulates largely during the second year of postnatal life. Although the prenatal nutrition of the mother remains an important health care need, the point is made that unless nutritional adequacy is maintained for the infant and young child, physical and mental development will be impaired. One fortuitous study based on the Dutch famine of the winter of 1944–1945 suggested that prenatal malnutrition in itself, although it stunted the brain growth of the fetus, was not associated with demonstrable diminution of mental competence during adult life.

The book presents a helpful four-level multisystem approach to nutritional problems. First of all is the capacity of the world to provide food. The current shift from a global food surplus to scarcity is a harsh reality that must be faced. The World Health Organization estimates that 50% of the world's children are undernourished. At the second level is the degree to which food is available to family units within a given country. Where there is a tendency toward urbanization and an allocation of food on the basis of income, starvation can occur in the face of national abundance. At the third level is the family's ability to nourish its children, the failure-to-thrive syndrome illustrating what happens when there is a breakdown in a family's ability to provide adequate nutrition for a child. At the fourth level is the child's own contribution to nutritional deficiency, either through the presence of disease, such as cystic fibrosis, or psychological impediments, as illustrated by anorexia nervosa and oppositional feeding disorders.

It is likely that the remarkable resilience and adaptability of the human species accounts for the less than totally devastating long-range effects of early childhood malnutrition. Most sobering, however, is the fact that, although there is a quantitative difference, there is no qualitative difference in malnutrition between the United States and underdeveloped countries. Whether it be kwashiorkor in Africa or the failure-to-thrive syndrome in America, the impact on the child is the same.

For the clinical psychiatrist, this book calls attention to malnutrition as yet another potential source of insult to the CNS, highlighting the need to carefully evaluate the nutritional aspects of a child or adult's background. At the same time, this book succeeds in making the point that even under circumstances of extreme malnutrition, social and family factors are critical in the cause and remediation of later developmental deficits. The inseparability of the CNS and its environment is once again demonstrated.

JACK C. WESTMAN, M.D.
Madison, Wis.

The Mentally Retarded Citizen and the Law, *edited by Michael Kindred, Julius Cohen, David Penrod, and Thomas Shaffer; sponsored by the President's Committee on Mental Retardation. New York, N.Y., Free Press (Macmillan Publishing Co.), 1976, 692 pp., $18.95.*

Any major new work on retardation stimulates curiosity about former attitudes and practices. For many years the primary reference work on retardation was Treadgold's *Mental Deficiency*, first published in England in 1908 (1). Reading Treadgold provides a perspective on what has changed and

what has not. Treadgold's dedication still rings true with proper humane concern: "To all those persons of sound mind who are interested in the welfare of their less fortunate fellow creatures."

Curiously, the tables of incidence of retardation, or below-average ability as it now is called, show only a little difference between the 38–40 per 10,000 in England at the turn of the century and the 30–35 per 10,000 in the United States today. Treadgold was interested in legal issues, which are still of concern, and made the following interesting comment:

> For my own part, I'm convinced that the nation which wishes to escape degeneracy will sooner or later have to give serious attention to the matter of the innate constitution of its citizens, and the manner in which that innate condition may be controlled by laws concerning marriage. Nevertheless, I do not think that any legislation on these lines is possible at present, for two reasons: firstly, because the laws regarding hereditary transmission are not sufficiently known; and, secondly, because we have no data regarding the antecedents of the mass of the people. (1, p. 538)

On the other hand, the issues of concern have shifted considerably. Treadgold's text is overwhelmingly preoccupied with taxonomy, classification, and clinical descriptions of the rarest forms of retardation, even though it acknowledges that these are of the least social significance. Of the 600 pages, only 10 relate to the laws concerning "amentia," only 23 to treatment and training, 32 to sociology, and a scanty and not very useful 2 pages on remedial measures in the psychosocial sense.

Even at the turn of the century, however, the mentally retarded were recognized as present and future citizens. Today this is reflected in the change of name of the National Association for Retarded Children to the National Association for Retarded Citizens. Treadgold tersely commented on society's obligations to these citizens throughout his text, but one comment, still applicable, is interesting enough to be repeated: "How illogical is the system which spends thousands upon the training of mentally defective children, and then turns them adrift to shift for themselves as best they can!"

In May 1973 the President's Committee on Mental Retardation held a conference to review progress as to the legal rights of mentally retarded citizens and to consider the obstacles to realization of these rights. The proceedings are published in this handsome, readable volume *The Mentally Retarded Citizen and the Law*. Psychiatrists will find much here that is useful; e.g., the development of concepts, legal and otherwise, related to the retarded have proceeded in parallel with those for the disturbed, but we are a far distance from the development of a National Association for Disturbed Citizens, even though, as children, they too represent the citizens of the future.

The book contains a bill of rights for the retarded which includes the right to life, education, choice of care, work, sex, family, and equal protection under the law. There are 22 primary position papers, each backed by comments on the positions taken. Even though the volume focuses on the law, it is particularly rich in pithy summaries of the current state of thinking about general issues of retardation. Usually these summaries are in the form of editorial comments binding the separate papers together; by themselves these commentaries are useful to the psychiatrist.

Other useful parts of the book include a chapter by Sorgen on labeling and classification, which is a wonderfully concise summary of the history, attitudes, and current state of mental retardation in the United States. Effland's section on "Trust and Estate Planning" and Heckt's comment on it are excellent presentations of the lawyerly skills needed to manage complicated medical, social, and legal issues. Price's comment on the "Right to Community Services" is a clear reminder and warning of the dangers as well as the seductions of community-based services. Bogg's section on "Quality Control of Community Services" is immediately relevant to psychiatric services in the community, as is Chambers' "Least Restrictive Alternative." The sections range from the craftsmanlike, with sharply defined issues and specific implementable suggestions, to those mainly representing the passionately indignant but informed advocate.

Generally, the papers avoid the use of special languages, tending to see specialness in language as hindering understanding among disciplines. On the other hand, the comments too often simply supplement the position papers; i.e., they are amens rather than critical assessments of positions taken. Perhaps it is too much to ask that a fox could have been invited into the chicken coop, too much like inviting a distiller to a Baptist convention. The guests might have tempered some of their advocacy and shed more light. Indeed, the resources are limited and priorities must be made.

Although the authors pay a great deal of attention to the rights of the below average and to the availability of the least restrictive alternative, they do not pay any attention to the similar rights of the average and the above average to the same least restrictive alternative. Perhaps it is the conflicts that keep progress toward common goals at an agonizingly slow pace. Only once, in a section on zoning restrictions, is there a glimpse of the "other side": Deutch argues his objections as a neighbor to group homes and the right of the retarded to live in the community. Even here, however, advocacy takes precedence over working through the resolution of conflicts generated and the solution of complex human problems.

HAROLD BOVERMAN, M.D.
Davis, Calif.

The Origin of Consciousness in the Breakdown of the Bicameral Mind, *by Julian Jaynes. Boston, Mass., Houghton Mifflin Co., 1977, 446 pp., $12.95.*

This is a fascinating book to read. In his range of interests Jaynes includes neurology, archeology, ancient history, and modern social phenomena. He has the reportorial skill of a Tolkien. In his rhetoric he is as startling as Freud was in *The Interpretation of Dreams*, and Jaynes is equally adept at forcing a new view of known human behavior. Whether he will be as successful as either Tolkien or Freud remains to be seen, but it seems to me that the potential is there.

The term "bicameral mind" might be unfamiliar to some readers. "Bicameral" means two chambers, of course, and Jaynes uses it to refer to the left and right temporal hemispheres of the human cortex. Those of us who studied our

neurology some decades ago are generally aware that speech mechanisms are located on the left (in right-handed people). Although the right hemisphere could take over some functions of the left if the left were injured, we were taught that speech was the exclusive province of the left. This assumption has changed on the basis of massive neurological researches in the last two or three decades. For example, there is growing evidence that intuitive as opposed to deductive comprehension seems to be located on the nondominant side of the temporal cortex and that the dominance of the right side shifts during some sleep activities. The famous Penfield experiments provide additional examples.

Starting primarily with Penfield's work, Jaynes develops the thesis that until 3000 B.C. mankind was bicameral and that bicameral man spoke and acted out of impulses originating on the left cortex (in the right-handed) but received the impetus for any such action from the right cortex. The impetus from the right was not in the form of visual or motor activity but was experienced as actual sounds—voices heard within—dominating and controlling man's activities. The right cortex was especially active whenever man was faced with a stressful situation, either threatening or unprecedented. The voices were direct, often correct, and followed as if direct orders. It is not clear whether these voices were first believed to be part of oneself or voices of the gods; it seems clear to Jaynes that they were soon understood to be from the gods.

When this primitive system brought animal-like carnage and destruction to much of the world (there was no mercy, no pity, no comprehension of others, merely narcissistic pillage), the voices, so like the voices of the schizophrenic patient today, occurred less and less. At this point, when man could no longer act, feel, or behave as a direct response to his voices, he was forced to introspect, to take some responsibility for his own actions, even hiding them or inhibiting them, if appropriate to this judgment of the situation. This is the origin of consciousness.

Of course, the development of adequate consciousness is still going on and often fails, but Jaynes believes the environment is capable of influencing the brain, in the manner just described, so he is optimistic for the future. However, he paints a drab picture of the thousands of years of disparate attempts to reinstitute the lost voices of the gods. He devotes the last section of this book to present-day survivors of the bicameral mind: hypnosis, religious conversion, schizophrenia, and all the magical efforts to learn what to do—from the auguries of astrology to the auguries of scientific mysticism.

The central section of this book is a Tolkien-like excursion through *The Iliad* and *The Odyssey*. Jaynes feels that the former is bicameral in that action is direct, never devious or introspective on the individual level, while the latter represents the struggle away from bicamerality toward consciousness. However, Jaynes presents archeological data, poetry, and ideas from so many disciplines that the reader begins to wonder how "one small head could hold all that he knows." I doubt if there exists a reader sufficiently skilled in all of these disciplines to know how to evaluate this book.

In neurology, I feel that Jaynes cites Penfield too literally and fails to cite other recent experimental work, especially that having to do with the immense interconnections among other portions of the brain besides the temporal cortex. In psychiatry, Jaynes seems more oriented; he uses and cites the pertinent recent researches.

The book is never dull. It forces a revision of customary thought patterns and may be germinal. It is not a book for readers seeking more data in a particular field of thought, be it behaviorism or psychoanalysis. It will be stimulating and provocative for all other readers. This book was reviewed in the *New York Times* (March 13, 1977) by Gerald Jonas, who, according to the *Times*, "comments regularly on science fiction."

RAYMOND HEADLEE, M.D.
Milwaukee Wis.

Chronic Childhood Disorder: Promoting Patterns of Adjustment, *by Ivan Pless, B.A., M.D., and Philip Pinkerton, M.B., M.D., D.P.M. London, England, Henry Kimpton (Chicago, Ill., Year Book Medical Publishers, distributor), 1975, 240 pp., no price listed.*

In his foreword to this excellent book, Dr. Robert Haggerty reminds us that chronic disease is the major health problem of children today. Drs. Pless and Pinkerton have pulled together a vast amount of information about the many sorts of chronic disorders that afflict children, and they have done it in a concise, organized, and clear way that I found both illuminating and a pleasure to read.

The authors deal first with the concept of adjustment, presenting an integrated model of adjustment to chronic disorder. They are aware that their particular idea of a "significant" and "causal" relationship between maladjustment and chronic disorder may be argued against, but they feel that the wide-ranging evidence they present might best help the clinician caring for these children. In discussing the assessment of adjustment, they show a careful effort to evaluate many studies on the subject and many points of view. This is a difficult task, but I found the well-reasoned and dispassionate tone of the authors reassuringly sensible. There is no feeling that special theoretical views are being adhered to at all costs, and as Dr. Tizard mentions in his foreword, "There is . . . a marked agreement in the findings of many investigators, working more or less in ignorance of each other and concerned with children (and families) whose diagnoses and disabilities are apparently very different."

Pless and Pinkerton cite studies that reflect the long-term impact of chronic disorder on adolescents and adults. They remind us again of the need for early intervention to try to minimize difficulties in scholastic and vocational adjustment. There is an excellent chapter on short-term adjustment to chronic disorder; this is divided into sections on such general issues as scholastic adjustment of the large group and on specific problems of particular disorders, allowing the reader to review areas of his or her own interest.

The final chapter takes up the subject of therapeutic intervention to promote adjustments, carefully breaking down the determinants, strategies, and emergent principles of intervention. Finally, the authors reemphasize that the key to successful treatment is the positive relationship of confidence and trust among physician, patient, and family.

This is a relatively short volume that impresses me as containing a great deal of well-thought-out information, presented in an easy style, and including an extensive bibliography. The book should be valuable to pediatricians and to a wide range of physicians caring for disabled children. It should certainly be of interest to the growing number of people involved in the care of chronically disabled children—nurses, nurse practitioners, and physician assistants, for example. I feel it is a particularly good book for medical students learning about disabled children, not only because of the clarity of

its presentation but because it presents a picture of the need for an understanding of all that goes into the care of chronically ill children, written with concern and a broad grasp of the issues.

CHESTER C. D'AUTREMONT, M.D.
Boston, Mass.

Pharmacology of Sleep, *edited by Robert L. Williams and Ismet Karacan. New York, N.Y., John Wiley & Sons, 1976, 347 pp., $26.00.*

This highly condensed volume of papers includes both extensive reviews and specific clinical studies. It represents a useful addition to workers in this field. Some chapters, such as "Concepts and Constructs About Sleep" by Salamy, are superb summaries of the entire field up to the present moment. Chapters like this are quite useful to new workers because they can quickly go over what has been discovered and its history and be brought up to the frontier of what is being worked on at the present time.

Most of the chapters suffer from the problem of breadth and insufficient depth. The review of drug effects by Kay and associates covers studies on a large number of drugs and their effects on sleep but gives no clear critical comments about these studies or a summary that could serve as a guide to the practicing physician. Indeed, there is such a preponderance of abbreviation in this chapter that there is a page of summaries of the various abbreviations used. This abbreviation page is an index of one of the problems of this volume—to whom is it addressed?

It is fairly narrowly addressed to workers in the area of sleep and drugs, despite frequent attempts throughout the volume to make it useful to the clinical pharmacologist. A brief concluding chapter about poor prescription practices represents an attempt to make it useful to the psychiatric or general medical practitioner, but this falls short of being truly useful.

In summary, the vast amount of work that has gone into this volume and the material it covers make it useful for libraries, but it is not a volume for purchase by the individual practitioner unless he or she is specifically working in the area of sleep and pharmacology. Even then the practitioner may elect to use it more for its bibliographic completeness than for the quality of the articles.

ROY M. WHITMAN, M.D.
Cincinnati, Ohio

Psychiatry. Medical Outline Series, 3rd ed., *by Merrill T. Eaton, Jr., M.D., Margaret H. Peterson, M.D., and James A. Davis, M.D. Flushing, N.Y., Medical Examination Publishing Co., 1976, 487 pp., $9.00.*

This book, now in its third edition in the United States and published simultaneously in six other countries, deserves its popularity as a concise review of psychiatry in a manageable size. Although the authors suggest that it might also be used as an introduction to clinical psychiatry, its succinctly didactic style, often accompanied by dogmatic statements, may tend to alienate those for whom this book is their first contact with our specialty. Having expressed these concerns, I can highly recommend this text as an ideal refresher and review of the essentials of personality development, psychodynamics, nosology, and the major clinical entities.

The discussions of psychotherapy, the somatic therapies, and psychiatric practice in community facilities are pertinent, relevant, and significant for modern-day practice. In the area of psychopharmacology, advances in neurochemistry and pharmacokinetics are being made with such rapidity that it is nearly impossible for any general textbook to be sufficient in itself because of the publication time lag. Up-to-date information about such clinically significant areas as drug dosage, methods of administration, blood levels, and clearance need to be supplemented by other resources, such as journal articles.

There is a very helpful chapter on psychiatry for the primary or family practice physician that includes advice on how to make referrals to psychiatrists, other therapists, or community facilities. There is also a chapter on forensic psychiatry and what I think is an overly foreshortened glimpse of the history of psychiatry. The legal chapter not only includes the usual elucidations of criminal responsibility, testamentary and contractual capacity, confidentiality, and involuntary hospitalization but also discusses the increasingly important aspects of medical ethics.

At the end of each chapter there are review questions that require both factual knowledge and some original creative and judgmental thinking to be answered comprehensively. The final chapter, titled "Reviewing for Board Examinations," is a storehouse of fairly good advice on testsmanship interspersed with an occasional touch of inelegant advice, e.g., for factual data to be memorized one may use "the inside of the bathroom door . . as a good bulletin board for such things (if you have a tolerant spouse)." This is concluded with a long multiple-choice examination composed of 165 test items and their correct responses.

The bibliography has been updated from the earlier editions, but it is somewhat sparse in parts. The authors do not presume to present this book as a substitute for the more voluminous comprehensive texts. In sum, there is a richness of information in this relatively small book, presented in a lucid and readable style that can serve as an excellent review of clinical psychiatry for medical students, physicians, and psychiatric residents, especially those preparing to take state or specialty board examinations.

S. MOUCHLY SMALL, M.D.
Buffalo, N.Y.

Obsessional Neuroses: Developmental Psychopathology, *by Humberto Nagera, M.D. New York, N.Y., Jason Aronson, 1976, 222 pp., no price listed.*

Psychoanalytic theories have been altered and transformed since Freud's earliest discoveries. The cornerstone of psychoanalytic theory, however, has remained the clinical study of individuals with varied disturbances. More abstract conceptualizations, some going beyond the clinical dimension, have emerged from such clinical investigations. Some of these changes were directly initiated by Freud and others by his colleagues, students, and successors. Despite these applications and extensions, psychoanalysts are still intimately linked to their patient work.

Obsessional Neuroses approaches these disorders from the developmental point of view—a perspective that has characterized the research of the Hampstead School established by Anna Freud. Dr. Nagera worked for many years as a close colleague and student of Anna Freud. In fact, this

monograph is presented as a tribute to her on the occasion of her 80th birthday.

Nagera has written many other psychoanalytic essays, reports, and books. In this treatise he presents the systematic study of one of the classical disorders originally investigated by Sigmund Freud. Nagera's talent for clearly organizing and stating his own views as well as those of others makes this volume very readable. He begins with a review of Freud's formulations and theoretical discussions that is comprehensive yet not complicated. Appropriate references and quotations allow the reader to follow Freud's development of thought as his experience increased. The second chapter is equally comprehensive in its coverage of the contributions of other psychoanalysts to our understanding of obsessional neuroses.

In the following chapters, the author explains his current theoretical positions and then devotes a chapter to three in-depth clinical examples. The cases selected are those of younger children and adolescents. These reports are well organized and carefully presented; the reader can closely follow the assessment of the patient initially and during the treatment process. It is my belief that this clinical chapter will be of great use to students as well as more experienced clinicians. It can serve as a model for meaningfully condensed and ordered clinical reports as well as a source of data. A comparison of obsessional and hysterical personalities, a discussion of the developmental approach to psychopathology, and a concluding chapter on general and diagnostic considerations complete the volume. The bibliography is appropriate, as is the index.

The foreword by Anna Freud is an excellent overture to the book. Sigmund Freud characterized the obsessional neuroses as the most interesting subject of analytic research. Some may have found other areas of analytic study to be of equal interest, but Nagera's book positively buttresses Freud's observation. This monograph is highly recommended to serious students, researchers, and clinicians.

The Creativity Question, *edited by Albert Rothenberg and Carl R. Hausman. Durham, N.C., Duke University Press, 1976, 366 pp., $14.75; $7.95 (paper).*

The editors, a psychiatrist and a philosopher, have assembled brief excerpts from the contributions of 45 people on the subject of creativity. These span 2,000 years and an equivalent diversity of disciplines; they would be cumulatively chaotic were it not for a considerable editorial effort to organize them so that they illustrate the development of the various contemporary attitudes toward the subject. Even so, the thesis that all this material relates to a single subject is so bewildering that halfway through the book I began to suspect the editors of cleverly arranging a test of my own creative ability. Perhaps after a suitable period of incubation I was to attempt that novel synthesis of apparently unrelated material which many assert is the mark of creativity. With dismay I realized I was failing; I heard a babel of definitions, approaches, and bits of theorizing instead of a beautiful synthesis.

How can a phenomenon (creative people and products) whose definition is so thoroughly subjective be studied? The approaches in this book range from the most sublime and awesome to the most banal and redundant. Plato refers to the work of genius that is said to derive from divine or supernatural motive forces. At the other extreme are those who define a creative person as one who makes unusual responses on psychological tests, those who are intent on teaching problem-solving skills to schoolchildren and businessmen, and those whose "theories" are little more than reductionistic dichotomies. I concluded that creativity is one of those subjects about which much is written but little is known.

Given the Herculean task the editors have undertaken, they have done a good job selecting and organizing the excerpts, introducing each with a succinct summary and providing an overall frame of reference with which to view them. In making an attempt to embrace both diversity and brevity in a single volume, however, the editors invite criticism about whose work they have included, whose they have omitted, and which fragment of a person's work is considered representative as well as skepticism about the result of condensing whole books and papers by such people as Plato, Aristotle, Freud, Rank, Jung, and Bergson (to name a few). From a psychoanalytic perspective (1), I think the Freud excerpt is not representative. Such seminal thinkers as Greenacre are not included at all. On the whole, however, the book is an interesting introduction to the almost anarchic diversity of writing on creativity; it would make an excellent source text for a course.

The book stimulated me to conclude that there may be many creativity questions rather than just one, as the title implies, and that they remain to be differentiated. Some may be more fruitful to pursue than others, and it is my guess that these are not the grandiose questions that have lured so many people of genius to speculate about creativity. Indeed, the more a phenomenon is truly original rather than merely unusual, the more the approach to it may be limited to retrospection, if any approach is possible. Phenomena that are unusual but not unique may be susceptible to attempts at predictive as well as postdictive understanding.

The Bergson excerpt most compellingly states the case that a creation is novel, unfamiliar, and to a significant extent removed from the deterministic realm. Therefore, the genuinely creative, as contrasted with the merely unusual, may pose an unanswerable question.

Houdini: A Mind in Chains. A Psychoanalytic Portrait, *by Bernard C. Meyer, M.D. New York, N.Y., E.P. Dutton & Co., 1976, 192 pp., $10.00.*

How does one review a "psychoanalytic portrait" or a psychohistory, particularly when one is neither a psychoanalyst nor a historian? It would seem one may do so by judging the accuracy and thoroughness of biographical data, the style, the content regarding the subject and related elaborations, and the cohesion and apparent logic of psychoanalytic speculation. Certainly Houdini (born Ehrich Weiss) is one of the most fascinating of men—a narcissistic, grandiose, mean, egocentric, daring, expansive person whose life

was riddled with unique psychopathology and unique accomplishment.

He led a magical life, transmuting magical thinking into action. As a magician, escapologist, actor, and writer, he played so many roles that the "real" Houdini remains a wispy character who cannot be readily grasped. Meyer has a psychoanalytic heyday with Houdini's denial of death and mortality, the symbolism of his feats, his castration and anxiety fears, preoccupation with rebirth and resurrection, ambivalence, sibling rivalry, multifold identifications, and counterphobic tendencies. Above all and encompassing all is the odd romance between Cecilia Weiss and her adoring son Ehrich. Whatever one's background and attitude toward psychoanalysis, one can readily see Oedipus wrecks in the shambles of the relationship of Houdini and his mother.

Houdini's works are replete with womb to tomb entrapments and liberations, dismemberments and reincorporations, denial of death, vacillating spiritualism, and God playing. This bizarre, childless man, whose activities symbolized everything from erection to resurrection and from bondage to ectoplasmic liberations and preoccupations, was the first to fly an airplane in Australia.

With all this exotica, Houdini comes across as an empty human; when the character armor is removed, there is little underneath. Many observations are based on known biographical data; others are speculations derived from psychoanalytic theory. In spite of the fact that Houdini's psychodynamics seem blatantly in keeping with traditional Freudian sexual theories, little seems to be known about his actual sexual life and practices. Perhaps more could have been said about the cultural determinants in this son of a poor Jewish immigrant (a rabbi in the midwest), one of many of the rabbi's children who married Christians, who was so uncharitable, untrusting, and unable to share and yet who had an affinity toward the mentally ill and the criminal.

Meyer's vocabulary is imposing, and often the writing is most artful, although, as with much psychoanalytic prose, it is repetitious at times. There are digressions to various personalities who impinged on Houdini's life, including the Conan Doyles of Sherlock Holmes fame. Interestingly, Meyer's son, Nicholas, introduced Sherlock Holmes to Sigmund Freud in *The Seven-Per-Cent Solution* (1). Bernard Meyer blurs the distinction between biographical reality and fiction when he states in a footnote, "Recent investigations indicate that in 1891 Sherlock Holmes was in Vienna, where he was treated for cocaine addiction by Sigmund Freud" (p. 159).

This book is an interesting look at a fascinating person who seems more fictional than real. After reading *Houdini: A Mind in Chains*, one is stimulated to want to know more about what he was really like when he was not acting. This psychoanalytic scrutiny is enlightening, entertaining, and informative, although possibly fraught with some unfounded speculation. The reader is likely to feel somewhat unsettled by the biographical and psychological developmental gaps. Perhaps an alternative title could have been *The Seventy-Per-Cent Solution*.

Successful Psychotherapy, *edited by James L. Claghorn, M.D. New York, N.Y., Brunner/Mazel, 1976, 203 pp., $12.95.*

This book is a collection of papers given at the 1975 annual symposium of the Texas Research Institute of Mental Sciences in Houston. The contributors include well-known authorities in the field. Its scope is broad, and, in the words of its editor, it has an eclectic, deliberately ecumenical outlook. According to Dr. Claghorn, "The recipe for intervention can now be viewed as multiple and as varied as the needs of the patient." In keeping with this, the authors offer a range of approaches, emphasizing issues and techniques currently enjoying special interest, all of which are given approximately equal standing. The selection is therefore fairly representative of current trends in American psychiatry. This makes for variety and liveliness but not for cohesiveness. In fact, the reader may find himself or herself stimulated by the diversity of the chapters but wishing for more unity and continuity in content and philosophy.

A look at the topics covered should serve to clarify this impression. There are papers on psychotherapy research (e.g., on the assessment of outcome, therapeutic components, and forms of helping alliances); integrating psychotherapy and pharmacotherapy in the treatment of schizophrenia and the neuroses; management of chronic psychotic patients; the psychotherapeutic technique of "reframing"; family therapy in anorexia nervosa; sex therapy; and the treatment of women, black people, and the poor. This selection represents a large enterprise for a book of just over 200 pages.

Successful Psychotherapy deals not so much with the actual conduct of psychotherapy or its inner complexities as with its relation to other elements of treatment (e.g., drugs, behavioral techniques, and the impact of social forces). Even though Hans Strupp cautions on this very point, one notes overall a tendency to speak of psychotherapy generically, as if it were all of a kind. This is most noticeable in the discussion of the usefulness of combining psychotherapy with other modalities of treatment, which the editor and several contributors regard as the coming practice. There seems to be an assumption that all psychotherapy is equally capable of being combined with other treatments. However, although it is evident that supportive, "relationship" therapy mixes readily with pharmacotherapy, other modalities, such as psychoanalytic psychotherapy, may not mix so well. This certainly is one of the many questions about psychotherapy that calls for study.

The book contains its fair share of stimulating and worthwhile presentations. Of special interest is the section on psychotherapy and social issues. Matters of controversy are treated reasonably and with restraint. For example, writing on depression in women, Myrna Weissman suggests that a prime factor may be the status of women in society and their "learned helplessness." She bases her argument primarily on the finding that depression appears to be more common in women. Although she does not present her views as assertions and is aware that methodological problems abound in this area of research, she also does not quite confront the question of whether depression is really different clinically in women and men. The basis for the difference in prevalence, if it is a valid difference, remains unclear.

Also of interest is a paper by Alvin Burstein on psychotherapy for the poor. With liveliness and humor he challenges two propositions that became instant dogma in the late 1960s. One is the idea that insight psychotherapy is only

for middle-class patients, and the other is the claim that indigenous paraprofessionals can substitute cultural congruence for technical training.

The examples cited above should suffice to convey the flavor of the book. *Successful Psychotherapy* offers the reader a good cross section of American psychiatry in the mid-1970s.

PIETRO CASTELNUOVO-TEDESCO, M.D.
Nashville, Tenn.

Personality, *edited by Rom Harré. Totowa, N.J., Rowman and Littlefield, 1976, 246 pp., $17.50.*

This book consists of seven essays organized into three sections on personality acquisition, description, and assessment. Although most of the essays have been published elsewhere, the material is not likely to be familiar to readers in the United States. Most of the contributing authors are British, and their ways of thinking about personality and personality research are quite distinct from the view of these subjects in the United States. In fact, the book can fairly be seen as a response to Walter Mischel's impressive attack on trait theories (1) by a group of personality researchers who, for good reasons, were unwilling to join him in embracing situationism as an alternative. In *Personality*, we have efforts to redefine the problems that the personality researcher seeks to solve, to create new methods of investigation, and to employ new explanatory constructs with sounder theoretical underpinnings than those used in the past.

Two articles discuss the issue of personality consistency directly. Alston provides a careful textual analysis of Mischel's work, and Argyle presents an interesting and well-organized review of the empirical research. Argyle then introduces a generative-rules approach to social behavior borrowed from psycholinguistics and discussed too briefly to have a real impact. Ziller offers a hierarchical theory of personal change that integrates disparate research in attitude change, behavior change, role strain, and self-concept. Clinicians will probably find this chapter to be the richest of the seven in its implications for their work. Other authors and topics include John Bowlby on the child's acquisition of self-reliance, Harré on the social and psychological aspects of personal names, and Shotter on what he calls the development of personal power as opposed to natural power in children.

A unity of sorts runs through these articles. All, or nearly all, express dissatisfaction with the current state of personality research, all eschew "naïve experimentation," and all are willing to draw on a wide variety of disciplines (e.g., psycholinguistics and ethology) for conceptual and methodological help. In most cases, personality is not defined in intrapsychic terms but as a set of social competences; most of the problems of interest here would be considered within the domain of social psychology in the United States. The editor freely admits that none of the essays constitutes a finished treatment of its topic. Rather, they may be regarded as promissory notes that signal a change in direction in personality research and whose promise may or may not be fulfilled.

Although I welcome the novel approaches to the study of personality exemplified in this book, I have two criticisms. First, the reading level is generally difficult. Second, new terms are introduced at times without sufficient discussion of why older, more familiar terms are no longer suitable. Shotter's concept of personal power, for example, shares much in common with such concepts as internalization, ego autonomy, and socialization, yet there are no references to these concepts or to the research literatures they subsume. In the absence of such references one is left wondering whether the author runs the risk of rediscovering the wheel. More of a sense of continuity with earlier personality theories and research might have made this book more influential than it is likely to be.

Syracuse, N.Y.

The Bipersonal Field, *by Robert Langs, M.D. New York, N.Y., Jason Aronson, 1976, 462 pp., $20.00.*

According to Dr. Langs this book is intended to provide clinical data to substantiate the concepts he developed in his two volumes on *The Technique of Psychoanalytic Psychotherapy* (1). To do this he has edited and reworked audiotapes of psychoanalytically oriented psychotherapy seminars he conducted with a group of students. The case material in the book is thus gathered and presented by student therapists and then discussed by Dr. Langs with the students. Dr. Langs lucidly illustrates theoretical concepts and principles of psychotherapeutic technique by using the case material presented. Because the book contains many precisely documented and clearly discussed clinical vignettes, it gives an excellent and solid demonstration of some of the technical principles of psychoanalytically oriented psychotherapy. In addition to illustrating certain aspects of the psychoanalytic psychotherapeutic technique, the book also reveals Dr. Langs's method of teaching psychoanalytic psychotherapy.

The main criticism I have of this otherwise clinically and didactically useful book is that the author employs new words whose meanings differ only slightly, if at all, from the more usual and standard psychoanalytic terms. A significant portion of the book is spent defining and explaining these new words. I will mention and define a few of these unfamiliar terms as I summarize some of the valuable content of the book.

The author stresses that this book is a "major contribution toward the integration of the interactional dimension into classical psychoanalytic theory and technique." To promote this integration, he borrows the phrase "bipersonal field" from the Barangers. He uses this phrase metaphorically to describe "the interplay between the interactional and intrapsychic realms and between the patient and the therapist." The concepts denoted by the phrase "bipersonal field" have been handled effectively in the past by using such generally accepted and understood terms as "therapeutic interaction" and/or "transference situation." When Dr. Langs correctly stresses the central importance of considering the bipersonal field in psychoanalytic psychotherapy, he is reiterating Freud's emphasis on the central importance of the transference situation in psychoanalytic therapy.

A considerable and important portion of the book is taken up with clinical data that clearly demonstrate Freud's impor-

tant, but at times overlooked or forgotten, principle that the therapist should maintain a state of relative abstinence; that is, the therapist should avoid gratifying any of the patient's transference needs. Dr. Langs presents a strong and convincing argument for the maintenance of the strictest abstinence, but unfortunately he uses new terms to describe this old principle. By "framework," "boundary," or "frame" he means the realistic, therapeutic contract between the therapist and the patient. When he stresses that it is important for the therapist to maintain the framework, boundary, or frame, he means that the realistic, therapeutic contract between the therapist and the patient should be preserved to avoid gratifying the patient's transference wishes. Dr. Langs calls a break in the therapeutic contract a "modified frame"; there is a "misalliance" when, due to collusion between patient and therapist, the therapeutic contract is broken and curative efforts are avoided. By "misalliance cure" Dr. Langs means what Freud called a "transference cure" based on transference gratification.

The author uses the phrase "adaptational context" to refer to the patient's world situation, which is composed of inner and outer worlds. He refers to projective and introjective identifications as interpersonal analogues of intrapsychic projections and introjections, and he states that it is the therapist's "container function" to serve as the receptacle of such projective identifications.

In the last chapter Dr. Langs demonstrates with clinical material that some patient behaviors which could wrongly be interpreted as transference manifestations are actually reactions to real messages unconsciously sent by the therapist.

This book lucidly illustrates some important principles of psychotherapeutic technique. It should prove valuable to all psychotherapists.

FELIX F. LOEB, JR., M.D.
San Diego, Calif.

Progress in Behavior Modification, Vol. 3, *edited by Michel Hersen, Richard M. Eisler, and Peter M. Miller, New York, N.Y., Academic Press (Harcourt Brace Jovanovich), 1976, 342 pp., $18.00.*

This book represents the third in an annual series of original reviews of various topics in behavior modification. The editors promise a diversity of subjects, and this volume more than fulfills that promise by presenting topics as diverse as hypnosis on the one hand and animal analogues of treatment procedures on the other. The editors' rationale for these volumes is that "even the most diligent reader will find it difficult to keep abreast of all of the developments in the field." If the field has become as broad and far-ranging as the list of subjects indicates, one logical question would be, Is there anyone who wants to keep abreast of all these topics? To answer this question for myself I decided to read carefully every contribution, including some with which I have only passing acquaintance, such as animal analogues and learning disabilities.

The subjects in this volume can be divided into three areas: clinical applications (smoking, learning disabilities, sexual disorders, and classroom applications), discussions of research strategies (animal analogues of behavioral treatment procedures and analogue therapy outcome research with humans), and, finally, two theoretical discussions—one on a comparison of hypnosis and behavior therapy and one on transferring treatment effects outside of therapeutic settings.

The two theoretical discussions are excellent. The lead chapter by Spanos and Barber is alone worth the price of the book in synthesizing two large but hitherto unrelated bodies of research. The authors review Barber's well-known work on the illogic of the hypnotic state and nicely summarize the hypnosis research of the last 15 years. They then integrate this research with the growing literature on the importance of cognitive influences in behavior therapy and suggest a process they call "involved imagining" as critical to both the hypnotic state and many of the behavior therapy approaches (as well as other psychotherapeutic approaches). This line of reasoning makes excellent sense and should be studied by all who are interested in psychotherapeutic processes. The final chapter by Marholin, Siegel, and Phillips is also an excellent review of the difficult issues involved in determining that therapeutic changes occurring in the office, clinic, or school transfer to other settings, where these changes are most desired.

Lichtenstein and Danaher contribute a comprehensive and up-to-date review of smoking. After reviewing data on psychological and pharmacological ideas of why people smoke, they describe the different measures of smoking, including some new "breathalyzer" techniques, which provide more objective measures. A thorough review of various treatment strategies underlines the many failures in this difficult area, but the authors conclude by summarizing treatments that have been demonstrated effective and suggesting methods by which these treatments might be made more effective.

Copeland and Hall's chapter emphasizes recent shifts in the targets of research in classroom applications from controlling disruptive behavior to enhancing academic performance. They review the latest developments in accomplishing these goals. Lahey's chapter on learning disabilities also provides an excellent, up-to-date review of this area that should be of interest to physicians, psychologists, and educators.

In their chapter on sexual disorders Ascher and Clifford note that most sex therapy is not currently supported by controlled experimentation and that this forces them into a review of the state of the art of sex therapy rather than a data-based review of treatment effectiveness. The authors accomplish their goal by comparing the classification and treatment procedures of Wolpe, Masters and Johnson, Kaplan, and others. They follow this up with an interesting discussion on where this field is going.

Discussing basic research approaches, Adams and Hughes describe the purpose of animal analogue experiments as to learn something about the prediction and control of behavior as it occurs in more complex human environments. Borkovec and O'Brien review human analogue situations, most often subclinical fears. I harbor considerable doubt about the value of analogues of human treatment efforts; yet these chapters provide a very good review of these areas that is appropriately critical but points out where such approaches can be useful.

The diversity of chapters in this book indicates that behavior therapy is probably losing its identity as a unified approach and disintegrating into various subtopics, clinical entities, or areas that have traditionally divided the broad area of behavior change. This is the fate of all new approaches that have proved their usefulness and become integrated into

the various areas of specialization. I enjoyed reading every chapter in the book (the first edited book I have read in years that did not contain at least one poor chapter). It became apparent in doing so that whatever one's area of specialization, much can be learned from the successes and failure of clinicians and researchers working in other areas. From this point of view, this volume serves a useful function which is valuable to everyone working in the area of behavior change.

DAVID H. BARLOW, PH.D.
Providence, R.I.

The Reality Therapy Reader: A Survey of the Work of William Glasser, M.D., *edited by Alexander Bassin, Ph.D., Thomas Edward Bratter, Ed.D., and Richard L. Rachin, M.P.A. New York, N.Y., Harper & Row, 1976, 673 pp., $15.00*

In his foreword to this compilation Dr. Glasser says, "The material here will not stand by itself—it is designed to supplement my books, and all of my books, starting with *Reality Therapy*, are a necessary prelude to what is printed here." He goes on to say that even then one could not learn the technique of reality therapy from books without supervised instruction. He is probably right, but his caveat need not discourage the potential reader who wants an overview of Glasser's ideas and contributions.

Reality therapy rejects the concept of mental illness, the therapeutic relevance of the patient's history, the importance of unconscious conflicts, and transference. It emphasizes "the morality of behavior" and attempts to "teach patients better ways to fulfill their needs." If one is not troubled by the apparent ambiguity in denying that mentally ill people are sick (whatever that may mean; "sick" is derived from the Middle Irish *socht*, meaning "depressed") but referring to them as patients and offering them treatment, the basic ideas are not difficult to grasp.

The reader contains papers by 31 contributors, of whom 4, including Glasser, are physicians. The book is divided into six parts. The first is titled Glasser the Man and includes several papers by and about him as well as interviews with him from the *Los Angeles Times* and *U.S. News & World Report*. Part two deals with the theory of reality therapy and part three with its practice.

Part four, on education, contains papers reviewing Glasser's contributions to this subject, including those contained in his book *Schools Without Failure* (1). In advocating that schools eliminate the failure orientation, which he feels is destructive to the self-esteem of students, he does not favor the elimination of standards and requirements. The principles of reality therapy are used, partially through class meetings, to help students solve problems, develop social responsibility, and acquire a sense of self-worth.

Part five, on corrections, deals with the use of reality therapy in correctional institutions. Part six, on role playing, consists of transcriptions of three tapes of Glasser's role-playing sessions. All three are initial simulated patient interviews, and in each a main goal seems to be to establish a therapeutic relationship with a poorly motivated patient or client.

The papers chosen for this book uniformly reflect an enthusiasm for reality therapy. Although there are some comparisons of the theoretical basis of reality therapy with that of other treatment modalities, one does not find anything that might be regarded as a critical appraisal of Glasser's ideas. One also does not find studies comparing the outcome for people treated, educated, or corrected by Glasser's methods with control groups served by other means except for one wistful note about pupils in a school using reality therapy methods who had "not so far forged ahead in testable qualities." The author then mentions the limitation of the tests used and the fact that these students were not used to taking tests. Perhaps one should not expect a book called a "reader" to furnish critical appraisals or research data.

One might enjoy this book more by reading a paper or two at a time rather than reading it all at once because there is a tendency toward repetition, not just of principles but even of anecdotes. Although this may reveal one of my many biases, I wish that the proponents of new treatments would offer the treatment on its own merits, sparing us repetitious destruction of strawpeople (e.g., "a slashing, no-holds-barred attack on conventional psychiatry and its current psychodynamic Freudian foundation"). Instead of advocating the new treatment as a panacea, I wish they would attempt to establish the conditions for which, or the circumstances under which, the new treatment or treatment modification is most useful.

At the least, the reader of this book will get a general idea of what reality therapy is all about; at best, he or she will get a few ideas that can be applied in conventional, eclectic psychiatric practice. The reader who wants more than this, who, for example, wants to become a reality therapist, should heed the warning in the foreword.

Marital Communication and Decision Making: Analysis, Assessment, and Change, *by Edwin J. Thomas. New York, N.Y., Free Press (Macmillan Publishing Co.), 1977, 227 pp., $12.95.*

For the experienced behavior therapist, this book is an excellent review. It updates research and presents a step-by-step exposition of procedures to be followed for the assessment and modification of problems in the communication and decision making of married couples. Edwin Thomas is a leading researcher and clinician who has worked effectively in this area of marital counseling. He clearly states that the main target responses in this type of intervention generally turn out to be problems of verbal behavior with a locus in partner interaction. Thus he wisely does not proclaim this approach to be the panacea for counseling of all marital problems. He recognizes that communication problems are one aspect of the total concerns of family members. His emphasis on the correct selection of partners for this approach is that of an experienced clinician. There is a welcome absence of the hucksterism seen in several other recent publications pertaining to the communication area of marital interactions. In keeping with his measured approach is Thomas' recommendation to the counselor that he or she tailor his or her plans for modification procedures to each partner and each couple.

Thomas recognizes that "alpha" problems or referent conditions such as couple decision-making problems take precedence over the communication problem approach. This leads to his devoting an equal amount of space in this book to the remediation of decision-making problems between marital partners.

This is not a beginner's book. Clinical experience and a knowledge of the vocabulary that has developed in this field are necessary to read it easily and appreciate it fully. Many of the statements made here are not explained in detail; the author assumes that the reader has the background necessary for understanding unelaborated statements. To the dynamically oriented psychiatrist, the total acceptance of manifest content and the obliviousness to the latent content shining through material is at first disconcerting. However, when he or she recognizes that the author presents a specific approach to a limited, controlled set of conditions, the approach seems fair.

PETER A. MARTIN, M.D.

Psychosexual Problems: Psychotherapy, Counselling and Behavioural Modification, *edited by Sidney Crown. London, England, Academic Press (New York, N.Y., Grune & Stratton, U.S. publisher and distributor), 1976, 465 pp., $14.75.*

This book is directed at a broad audience, including not only psychiatrists and psychologists but social workers, counselors, welfare personnel, pastoral counselors, and general medical practitioners. Its principal aims are to "cover" psychosexual problems in groups of patients hitherto not considered (e.g., postsurgical patients and people with venereal disease) and to present principles of therapy and counseling for them. To accomplish these aims the 19 chapters are divided into four major sections: Sex Therapies, Psychosexual Problems and the Life Cycle, Psychosexual Problems in Medicine and Surgery, and Sex Education. All of the authors are English except for one Dane and one North American. The writing varies in style from quaint to scientifically terse to humorous verging on the sarcastic. The tone of this book is quite different from other current material on human sexuality because of its use of such terms as "frigidity" and "perversions" and its heavy emphasis on dealing with paraphilias rather than sexual disabilities in couples.

The first section contains 2 excellent chapters on behavioral and group treatment approaches to sexual problems. These chapters are clear, comprehensive, and highly informative. They are excellent examples of how behavior and group therapists work in general and how they apply their approaches to sexual problems in particular. The other chapters in the section on counseling and psychoanalytic approaches are elementary and rarely specifically relate to sexual problems.

The section on psychosexual problems and the life cycle is the weakest one in the book, not only because the life cycle is not covered but also because it lacks examples and represents a superficial, often antiquated approach to dealing with sexual problems.

The section on sexual problems in medical and surgical practice is very useful in that it deals with many aspects of sexuality not often discussed in other sources (e.g., surgical, urological, and obstetrical conditions). These chapters are usually to the point and clearly written, although they occasionally suffer from outrageous comments, such as, in referring to the attention paid to the clitoris, "To some extent this is a symptom of the West, where women are conditioned to expect orgasm unlike their Oriental sisters, or their simian cousins" (p. 375).

The section on sex education has a generally narrow and somewhat outlandish perspective; e.g., "In a nutshell perhaps the sexually transmitted diseases are best regarded as sports injuries" (p. 446). It is doubtful that any people opposed to sex education would have their opinion altered in the slightest by this section.

Overall, this book has some very positive aspects. It draws attention to the sexual implications of a number of areas hiterto not considered in depth, it reviews some areas of sex therapy very well, and it contains a wealth of information about sexuality. However, it does have problems. The book could have been greatly shortened if all the authors had agreed on one system of classification of sexual problems so that they each would not have had to describe his or her own and if they had not repeated the same material about counseling. There is an undue emphasis on dealing with sexual variations at the expense of covering such frequently seen problems as marital difficulties. The terminology used in the book sounds rather antiquated and could easily alienate many readers (e.g., the use of "frigidity" and "perversions"). It also shifts in its level of psychological sophistication from naïve to virtually confusing.

The book has several deficiencies that severely limit its usefulness. It does not review current concepts of sexual physiology (generally, the most recent reference it gives is Masters and Johnson's work published in 1966), nor how to examine a patient with a sexual complaint from a psychological and physical perspective and establish a differential diagnosis. Many chapters repetitively deal with limited aspects of this issue, but there is no comprehensive discussion of it. Nothing is mentioned about sexual attitude reassessment methods or the use of sexually explicit materials in sex therapy, except for the chapter on behavior therapy. With the exception of the chapters on behavioral and group approaches, a novice would have great difficulty figuring out what to do if faced with a patient who had a sexual complaint on the basis of what he or she learned from this book.

Keeping Patients in Psychiatric Treatment, *by Chaim M. Rosenberg and Anthony E. Raynes. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 161 pp., $16.00.*

The special interests of Rosenberg and Raynes are the epidemiological and sociological aspects of psychiatric care, with an emphasis on consumerism. The title implies and the contents of the monograph make explicit the failure of what the authors designate as "the official mental health treatment system" to provide an adequate array and deployment of treatment facilities to intercept people in psychiatric need and, more particularly, to keep them in treatment sufficiently long. The mental health planners are at fault for not surveying the varying needs of the community from area to area. Treatment personnel are at fault for organizing psychiatric treatment facilities that cater to their own personal needs as well as to those of their patients. In consequence of these faults the rate of catchment is pitifully low, and the rate of dropout following referral or assessment is very high.

However, the authors are aware that many dropouts are not caused by either poor planning or any fault of treatment personnel.

The volume comprehensively surveys demographic studies of psychiatric morbidity; the literature on social class in relation to psychopathology, psychiatric referral, and the congruence or incongruence of aims of patients and treatment personnel; and the contentious and the uncontentious papers on rates of spontaneous remission of the less severe psychiatric disorders. It deals with publications on the motivations and needs of patients, which are very different from each other. These several threads are brought together in a survey revealing the occasional success and the frequent failure of the official mental health treatment system to respond effectively to the myriad of variables, particularly the failure to keep the patient to the extent that keeping (an unfortunately chosen verb) is necessary.

The authors do not indicate toward whom they have targeted the book. They bring together a great deal of pertinent information but nothing essentially new to psychiatrists. What was novel 20 years ago in the Midtown Manhattan and the Stirling County studies and in the brilliant social-psychiatric work of Hollingshead and Redlich is familiar today. Little seems to have been added since beyond the predictable spate of studies filling in the details and providing illustrations of those pioneering perspectives of the psychiatric scene.

Perhaps the book is intended for lay planners (if there are any) of psychiatric treatment facilities. It has the persuasive and manifestly thorough quality of a commissioned report for some worthy governmental agency. It deserves a place in the libraries of health science departments and government departments of mental health.

It seems time (at least to me) that the accusation of self-interest on the part of health treatment personnel should be given this final airing and hereafter decently buried. Naturally, the motivations of physicians, nurses, social workers, etc., are mixed and include self-interest. Health professionals must be mentally and emotionally healthy if they are to do their jobs effectively, and this implies properly taking care of their basic personal interests, too. If anything, health professionals are more likely to be concerned with their own psychological and biological self-interests than to those of their clients at large. If they do, as the authors contend, so much the better.

DONALD J. WATTERSON, M.D.

Gilles de la Tourette's Syndrome, Vol. 1: International Registry, *edited by F.S. Abuzzahab, Sr., M.D., Ph.D., and F.O. Anderson, M.D. Minneapolis, Minn., Minnesota Medical Foundation, University of Minnesota, 1976, 220 pp., no price listed.*

This book is a compilation of papers presented at the 123rd annual meeting of APA in May 1970 or written by authors who could not make it to San Francisco that year. It is therefore dated.

The first section of the book presents an abundance of case histories from the University of Minnesota's international registry and other sources, but these are not drawn together in a way that would increase their usefulness to practicing clinicians or researchers. There are some fascinating observations, such as the increased movements and utterances associated with allergies and infections and reports of cases of Tourette's disease from China and Europe.

The second section of the book is most notable for its presentation of neuropathological findings of a Polish teenager who died in 1969 and the report of increased dopamine excretion before haloperidol (Haldol) therapy followed by return to normal levels after treatment. Unfortunately, the narrative report of decreased dopamine is not supported by the appropriate numerical data.

The third section is a single 16-page paper that puts the material in the previous two sections in perspective; this paper lists 508 references. The principal value of this volume lies in its comprehensive bibliography and as a repository for case histories of primary Gilles de la Tourette's syndrome. Most clinicians will find other sources more useful.

Report of the Secretary
Summary of Meetings of Board of Trustees and Executive Committee
May 1976–May 1977

IT IS MY final privilege as APA Secretary to report to the membership the deliberations and transactions of the APA Board of Trustees. With the invaluable collaboration of the Medical Director, Mrs. Ruth Arnold, and others in the Central Office, I have subdivided this report into several categories.

The first category concerns revision of the Constitution and By-Laws, which is immediately relevant for the information of and action by the membership. The remaining categories are listed in alphabetical order.

In true democratic tradition every member of APA is privileged to attend any session of any component of the Association except for the meetings of the Ethics Committee. However, when such personal appearance is impractical, I am sure your next Secretary, Dr. H. Keith H. Brodie, would welcome correspondence on any topic either for the direct attention of the Board of Trustees or for forwarding to the appropriate component for consideration and action.

Finally, I am deeply appreciative of the confidences you have placed in me and shall do my best to merit them in the future.

The Board (or its Executive Committee acting as its agent) took the following actions.

CONSTITUTION AND BY-LAWS

1. Withdrew its approval (given March 7, 1976) of the proposed Constitution and By-Laws. It took this action on the premise that it was irresponsible to offer the membership a document it considered less than its best effort because the Assembly had voted not to accept or reject any of the proposed Constitution and By-Laws changes in order to give the district branches opportunity for full consideration and because no member of the Board of Trustees was completely satisfied with the proposals. The Board urged reconstitution of the Joint Conference Committee on the Key Conference, with a mandate to proceed to develop a better document (Bd., May '76).

2. Adopted the following proposed charge to the reconstituted Joint Conference Committee on the Key Conference Recommendations as a guide: to review all relevant documents, reports, and critiques dealing with recommendations for changes in the APA Constitution and By-Laws emanating from the Key Conference deliberations and subsequent proposals for constitutional change; to note the legal opinions on the potential impact of the proposals for change; and to proceed as rapidly as practicable to draft a new document that deals with the concerns and criticisms expressed by the Trustees on May 9, 1976, when they rescinded the March 7, 1976, approval of the proposed Constitution and By-Laws (Bd., June '76).

3. Authorized publication of the Constitution and By-Laws in *Psychiatric News* (instead of the *American Journal of Psychiatry*) in the event that any one petition for amending the Constitution and By-Laws is presented on the 1977 ballot (Ex.C., Sept. '76).

4. Ruled unconstitutional a proposed amendment (by petition) to the By-Laws designed to transfer fiscal power for dues and assessments to the Assembly without a concomitant amendment to the APA Constitution (Ex.C., Sept. '76).

5. Accepted the Secretary's report of withdrawal of 51 signatures from petition documents A, B, C, and D to amend the APA Constitution and By-Laws and certification that this withdrawal constitutes invalidation of said petitions; they will not be on the 1977 ballot (Bd., Dec. '76).

6. Noted without formal action that it was the understanding of the Reference Committee that the present organizational structure represents minority groups best and therefore should always be presented by the Joint Conference Committee on the Key Conference Recommendations as one of the models for consideration (Bd., Dec. '76).

7. Accepted formally the Secretary's notice that he had received three documents, entitled A, A1, and B1, which were petitions to amend the APA Constitution and/or By-Laws; that each of the petitions was signed by more than the 50 required APA voting members and was received at least 60 days before the annual meeting; and that the signatures on the petitions had been checked and found to be valid (Bd., April '76).

ASSEMBLY

1. Endorsed the Assembly and Budget Committee recommendations that there be an orientation session for executive secretaries of district branches, to be held in 1977 and peri-

This is an edited version of the report presented by the Secretary to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

odically thereafter—perhaps every five years (Bd., Dec. '76).

2. Approved the recommendation of the Assembly and the Budget Committee that the revolving fund held by APA for divisional meetings could be put to better use by the areas, and endorsed the ideas of abolishing the divisional meeting fund and of sending funds to or holding them for the areas on request (Bd., Dec. '76).

AWARDS

1. Accepted with thanks the grant from the Foundations' Fund for Research in Psychiatry on or about July 1, 1977, to establish a new prize to be called the Foundations' Fund Prize for Research in Psychiatry, the requirements for which will parallel those for the present Hofheimer Prize, funds for which expire after 1977; the Award Committee will consist of six investigators who will be appointed by the APA President to serve three-year terms with staggered rotation dates. The first award will be made at the Convocation during the 1978 annual meeting (Bd., Dec. '76).

2. Established a new award, "The Founders' Award," which will be given annually to a member of APA who has made outstanding contributions as author, spokesperson, and publicist in the services of the mentally ill and disabled and to the art and science of helping them. A plaque and cash award of $1,000 will be presented at the Convocation at the annual meeting, beginning in 1977; funding will be provided by Lederle Laboratories (Bd., Dec. '76).

CONTINUING MEDICAL EDUCATION

1. Approved the expenditure of $5,000 for printing and mailing the continuing education packet to all APA members in September 1976 to explain the new requirement for continuing education activity; noted that the project would be supported by funds available in the Psychiatric Knowledge and Skills Self-Assessment Program revolving fund (Bd., June '76).

2. Authorized $3,200 for the Office of Education, to be used for funding a newly constituted Steering Committee for PKSAP-IV, funds to come from the Psychiatric Knowledge and Skills Self-Assessment Program revolving fund (Bd., Dec. '76).

3. Approved the recommendation of the Council on Medical Education and Career Development that district branches be encouraged to apply for autonomy as accrediting bodies (Bd., Dec. '76).

4. Approved as working guidelines the Policy Recommendations for CME Activities of the Committee on Continuing Education. The Office of Education, in consultation with the council and the committee, will oversee these activities (Bd., Dec. '76).

5. Approved the policy guidelines of the Committee on Continuing Education as follows: General Members and Fellows in active psychiatric or medical practice, administration, education, and research must comply with the CME requirements as part of APA's continuing thrust toward highest quality patient care; Inactive Members, Distinguished Fellows, and Honorary Members are exempt; and Canadian members and APA members from other nations will be held to the requirement for documentation of 150 hours of CME participation over a three-year period but will be exempt at present from adherence to the strict categorical distinction for these hours. (Legal opinion: Life Fellows and Life Members *not* in active practice of psychiatry are to be exempt from CME requirements; Life Fellows and Life Members so designated in the future be required to meet the CME requirements if they *continue* in active practice.) (Bd., Dec. '76).

6. Approved the recommendation of the Council on Internal Organization that any APA program of audio cassette continuing education for distribution to the membership be subject to controls in the selection of material recorded and review of the product before distribution, according to the Council on Medical Education and Career Development policies for audiovisual and audiotaping programs (Bd., Dec. '76).

COUNCILS, COMMITTEES, TASK FORCES, AND COMMISSIONS

1. Authorized 5-year staggered terms for members of the Commission on Judicial Action (Bd., Apr. '76).

2. Authorized the Board's Membership Committee and the Assembly's Membership Committee to meet and work together, under the auspices of the Assembly (Bd., June '76).

3. Authorized a change in the APA *Operations Manual* to incorporate the provision for emergency action by the Joint Commission on Government Relations that enables the President, the Speaker, and the Medical Director to collectively make policy decisions for action, consistent with APA purposes, subject to subsequent reporting to the Board and the Assembly (Bd., June '76).

4. Approved restructuring three components of the Council on Medical Education and Career Development: termination of the present subcommittee on continuing education; termination of the present subcommittee on education of psychiatrists and reconstitution as the Committee on Continuing Education; termination of the subcommittee on education of physicians and reconstitution as the Committee on Psychiatry and Primary Care Education (Bd., June '76).

5. Authorized the President to appoint an Ad Hoc Committee to Review *Psychiatric News* (Ex.C., Sept. '76).

6. Authorized the Ad Hoc Committee on Interprofessional Services to continue for one more year (Bd., Apr. '76).

7. Renewed three committees for another year: the Ad Hoc Committee To Plan a Conference on Law and Psychiatry, the Ad Hoc Committee on Election Procedures, and the Joint Conference Committee on the Key Conference Recommendations (Bd., May '76).

8. Terminated two ad hoc committees, with thanks: the Ad Hoc Committee on the Key Conference Recommendations and the Ad Hoc Committee To Revise the Constitution (Bd., May '76).

9. Approved establishment of an ad hoc committee under the Council on Medical Education and Career Development, with a charge to make recommendations as to the implementation of the 1976 referenda on psychiatric certification (Bd., May '76).

10. Approved the reappointment of Drs. H. Keith H. Brodie, John Davis, and Rebecca Solomon for second four-year terms on the Editorial Board of the *American Journal of Psychiatry* (Bd., Dec. '76).

11. Approved a recommendation of the Reference Committee that Trustees be assigned to each council in May on an annual basis to provide liaison from the Board to the

council and that Trustees so assigned attend meetings of the council throughout the year (Bd., Dec. '76).

12. Approved changing the name of the Committee on Conventions to the Committee on the Annual Meeting (Bd., Dec. '76).

13. Authorized the Task Force on Asian-American Psychiatrists to seek outside funding from HEW to develop a data information bank regarding the treatment of and programs for Vietnamese and Cambodian refugees with mental health problems (Bd., Dec. '76).

14. Voted against reestablishment of the Commission on History at the termination of its present tenure (May 1977) and requested the Museum and Library Committee of the American Psychiatric Museum Association to assume the functions of the present commission (Bd., Dec. '76).

15. Approved the recommendations of the Committee on Graduate Education that APA make every effort with academic organizations to arrange experiences in general medical training for psychiatric trainees in their first postgraduate year and that APA commend the ABPN for its cooperation and effective response in working toward solutions of difficult problems over the past two years (Bd., Dec. '76).

16. Approved establishment of a new Committee to Review and Coordinate the Functions of the Hospital & Community Psychiatry Service, members to include a representative from the Editorial Board of *Hospital & Community Psychiatry* journal and Institute Program Committee, from the Council on Internal Organization, and at least one other member; authorized continued financial support of these activities and development of mechanisms to assess the value of the components of the service to its members (Bd., Dec. '76).

17. Approved sending letters to the President and the Secretary of State expressing alarm about the persecution of the scientific and professional community in Argentina and urging the State Department to take such action as it can to meliorate the situation (recommended by the Council on Emerging Issues and the Council on International Affairs) (Ex.C., Feb. '77).

18. Took no action on a telegram sent by the participants of the APA's Symposium on Culturally Relevant Training for Asian-American Psychiatrists to Mrs. Rosalynn Carter urging appointment of Asian-American representatives to the President's Commission on Mental Health. The President wrote a personal letter calling attention to the needs of that group (Bd., Apr. '77).

19. Accepted the resignation letter of the Editor of the *American Journal of Psychiatry*, Dr. Francis J. Braceland, and his suggestion that the transfer of the editorship be made slowly and with all due deliberation; agreed with applause with President Gibson's words of appreciation for Dr. Braceland's taking "an excellent journal and making it even more excellent." (President Gibson announced that he would consult with President-Elect Weinberg and appoint a search committee) (Bd., Apr. '77).

20. Authorized the Joint Commission on Public Affairs to develop and refine a proposal that APA conduct public opinion and attitude research (Bd., Dec. '76).

21. Accepted the recommendation of the Joint Commission on Public Affairs that the Board reconsider its request for formation of a national advisory group to help promote an improved image for psychiatry; noted alternative suggestions and the statement that there is a definite need for a panel of advisors to the joint commission and for specialized advice and consultation by the Joint Commission on Government Relations; asked that the commission reconsider the whole issue and come up with suggestions (Bd., Dec. '76).

22. Authorized publication of "Guidelines for Psychiatrists in Their Relationships with Communications Media" in the Official Actions section of the *American Journal of Psychiatry* (134:609–611, 1977) with a goal of encouraging every district branch to have designated members available to the media (Ex.C., Feb. '77).

ELECTIONS AND TERMS OF OFFICE

1. Accepted the report of the Committee of Tellers; no candidate received the required 40% of the votes in three positions, and a run-off election to determine President-Elect, Vice-President, and Area I Trustee will be held (Bd., Apr. '76)

2. Asked the Ad Hoc Committee on Election Procedures to consider the matter of how members should conduct themselves in APA national elections, and suggested that a group or individual presenting any document be identified properly on the election publication and that the source of funding be identified (Bd., May '77).

3. Accepted the Committee of Tellers' report of returns in the May 1976 run-off balloting, certifying that Dr. Jack Weinberg had been elected President-Elect and that Dr. Alan Stone had been elected Vice-President (Bd., June '76).

4. Ruled, after closed discussion regarding the Area I Trustee election and run-off, that the procedures had been correct and according to form, affirming that, as reported by the Committee of Tellers, Dr. Ben Feather was elected Area I Trustee (Bd., June '76).

5. Authorized the President to appoint an ad hoc committee to review the constitutional provision for filling vacancies on the Board of Trustees (due to absence or illness); to discuss the election issues (policies concerning nonseating of an elected Trustee; policies, procedures, and the reasons for recall; issues surrounding seating and nonseating); to develop statements concerning challenges of various aspects of the election procedure and the time when a challenge may be filed; to discuss verification of biographical data on the ballot and who should be responsible for such verification; to investigate the complaint by members of Area I, evaluate it, report to the Trustees, and consider why the challenge had been delayed (Bd., June '76).

6. Elected Dr. Judd Marmor and Dr. Lewis L. Robbins as the two Trustees to serve on the Executive Committee of the Board in 1976–1977 (Bd., June '76).

7. Approved the recommendations of the Ad Hoc Committee on Ballot Biographical Data that the Board of Trustees has the power to fill any vacancy on the Board; suggested the matter of Area Trustee replacement be referred to the Committee on Constitution and By-Laws and to the Joint Conference Committee on Key Conference Recommendations (Ex.C., Sept. '76).

8. Approved the recommendations of the Ad Hoc Committee on Ballot Biographical Data that the Board of Trustees and not the Committee of Tellers declares a winner. If there is a previous complaint, the last time that its validity can be examined is before ratification; and, further, directed the Joint Conference Committee on Key Conference Recommendations and the Committee on Constitution and By-Laws to include provisions and policies in the new Constitution and By-Laws for recall of an elected Trustee and for recall elections (Ex.C., Sept. '76).

9. Approved the recommendations of the Ad Hoc Committee on Ballot Biographical Data regarding challenges of

various aspects of the election procedures and the time limitations thereto, with the request that the material be inserted in the APA *Operations Manual*, in the section on Election Procedures (Ex.C., Sept. '76).

10. Accepted the statement of the Ad Hoc Committee on Ballot Biographical Data with regard to verification of biographical data and concurred that the *Operations Manual* sets forth the procedure for presenting the preelection biographical data equitably but cannot be construed as a certification of accuracy and that the membership shares in the responsibility for correct data (Ex.C., Sept. '76).

11. Approved the stand of the Ad Hoc Committee on Ballot Biographical Data that the Board of Trustees acted properly in seating Dr. Ben Feather as Area I Trustee after the 1976 election and their recommendations that if there is any further disagreement with the Board's action, action can be taken to initiate recall, if there is as yet undisclosed evidence to support it; and asked that a notice be inserted in *Psychiatric News* stating that in future elections any objections to or questions on published biographical data be stated to the Board or Executive Committee as soon as possible (Ex.C., Sept. '76).

12. Accepted the approval by the Ad Hoc Committee on Ballot Biographical Data of the form currently used by staff to collect biographical data as the official form and their recommendation that biographical data be accepted *only* on that form (with a certifying statement that the information is correct at time of submission) (Bd., Dec. '76).

13. Accepted the recommendation of the Ad Hoc Committee on Ballot Biographical Data that, in the event of a runoff election, staff reverify the biographical data, making any necessary changes, and asked that members be urged to make complaints as soon as possible (Bd., Dec. '76).

14. Requested that the Ad Hoc Committee on Election Procedures meet with the Assembly at the annual meeting in May 1977 to try to work out the differences between the position of the Assembly and that of the ad hoc committee and the Board on preferential balloting (Bd., Dec. '76).

15. Approved the recommendation of the Ad Hoc Committee on Election Procedures that two statements be sent to candidates to assure compliance with the guidelines: the first statement to be signed by the candidate, acknowledging awareness of the guidelines and promising to abide by them, and the second statement to be signed at the end of the campaign, affirming that the candidate conducted the campaign within the guidelines (notice of compliance to be published in *Psychiatric News*) (Bd., Dec. '76).

16. Approved the recommendation that any campaign literature on behalf of a candidate must include a statement that the explicit approval of the mailing had been obtained from the candidate and a statement of the specific source of funding, with the further notice that personal attacks on candidates are prohibited (Bd., Dec. '76).

17. Approved the Ad Hoc Committee on Election Procedures' recommendations for penalties for campaign violations from most to least serious: admonishment and reprimand, with publication; disqualification from running for election; refusal to seat an elected officer (or unseating, if the violation is made public later); and referral to the Ethics Committee (Bd., Dec. '76).

18. Approved the Ad Hoc Committee on Election Procedures' recommendation that a standing Committee on Election Issues be appointed to handle all campaign matters; that any member accepting appointment will agree to refrain from running for office and from active support of any candidate during his term; and that complaints regarding alleged violations be mailed to the Secretary of APA, who will route them to the Election Committee for review and investigation, report back to the Board, and, where responsibility for a violation is found, recommend actions from the above penalties; and that the deliberations be recorded and forwarded by report to the Ethics Committee (Bd., Dec. '76).

FISCAL MATTERS

1. Approved the suggestion that APA refund a pro rata portion of dues of deceased members (Bd., June '76).

2. Ratified the emergency action of the President, in consultation with the Medical Director and the Speaker, to fund the second stage of the research project to study New Jersey psychiatrists re role conflict in psychiatry.

3. Suggested that the Budget Committee consider partially funding the Falk Fellowship Residency Program (Bd., Apr. '76), and one year later, on receipt of 1) the annual report of the program, 2) notice of a grant of $27,000 to continue the program this year, and 3) notice that the Falk Fund would continue its commitment only until August 1979, approved asking the Budget Committee to budget for full support of the Falk Fellowship Residency Program after the funding from the Maurice Falk Fund has ceased, with increased phased-in funding (Bd., Apr. '76).

4. Approved changes in APA's staff pension plan at an estimated annual cost of $10,000 and authorized staff to take steps necessary to implement these changes (Bd., Apr '76).

5. Approved the recommendation of the House Committee for construction of a doorway between the APA Central Office and Museum buildings and authorized proceeding with development of an alternative plan at a cost not to exceed $4,000 (Bd., June '76). Construction stopped when the House Committee determined the need for an architectural and engineering study of the present structures ($6,000 approved) and the need for exploring alternative means of meeting APA's housing needs in the Washington, D.C , area ($3,500 approved) (Bd., Dec. '76).

6. Approved the recommended 4.8% cost-of-living increase for APA employees retroactive to October 1, 1976, in accord with the policy of maintaining parity with the federal government (Bd., Dec. '76).

7. Reaffirmed the resolution that any council, board commission, or other component that contemplates increasing its costs must obtain Board approval (Bd., Dec. '76).

8. Authorized the Project Director of the APA Minority Fellowship Program and the Deputy Director for Business Administration to seek further funding to continue the program, either from the National Institute of Mental Health or other outside sources.

9. Approved the division of the $75,000 contingency funds (Ex.C., Feb. '77) made by the Treasurer and the Medical Director, and as instructed by the Budget Committee, as follows: Board of Trustees Contingency Emergency Fund, $60,000; and Medical Director's Emergency Operating Fund, $15,000 (Bd., Apr. '77).

10. Received information that the Treasurer had signed an application to the IRS to change the fiscal year of APA and APMA to a calendar-year basis, and noted that assuming IRS approval, the projection of income over expenses will be adequate to fulfill two mandates of the Board: to set aside an operational reserve on December 31, 1976, and to add to reserves from operations during the current fiscal period (Bd., Dec. '76). On April 1, 1977, received information that both APA and APMA had received authorization from the IRS to

change their fiscal year periods to a calendar-year basis.

11. Authorized expenditure of $8,000 from the Board of Trustees Contingency Fund during 1977 for initiation of a proposed Resource Development Project to identify needed improvements, identify sources of funds, develop promotional materials for the Association and the department or program involved, and present proposals to funding sources (Ex.C., Feb. '77).

INSURANCE

1. Reaffirmed the addition of $3,500 to the Assembly Budget for fiscal year 1976–1977 to support a Pilot Insurance Coding Project approved last year but not used (Bd., June '76).

2. Requested the Deputy Director for Business Administration to outline how a central nucleus might be established at the APA headquarters for insurance and other member benefits, and to draw up a cost analysis and model of operation to present to the Assembly and to the Board of Trustees (Ex.C., June '76).

3. Ratified the President's emergency action to approve the proposed retirement plan, contract, and related documents; authorized the Trustees of the APA Retirement Plan to finalize the arrangements as specified (Ex.C., Sept. '76).

4. Ratified the President's emergency action by authorizing an actuarial study of the Association's Professional Liability Program, at an estimated cost of $10,000 (Ex.C., Sept. '76).

5. Asked the President and the Speaker to appoint a small committee to meet with the APA Committee on Member Insurance during the Fall Committee Meetings and reexamine the entire issue of group insurance for APA members, and asked for a report back to the Board of Trustees (Ex.C., Sept. '76).

6. Approved establishment of tax-deferred annuity plans for eligible APA members and staff (Bd., Dec. '76).

7. Approved obtaining an insurance policy covering Association Professional Liability Risk Exposure for members of the Board, constituent components, and staff, at an estimated cost of $5,000 (Bd., Dec. '76).

8. Approved terminating the present Committee on Member Insurance and Retirement Plans, to be replaced by two components: Committee on Member Professional Liability Insurance (whose members would also constitute the Loss Control Committee and Committee on Member Health, Accident, and Disability Insurance), and the APA Retirement Plan Committee, to be responsible for the new member retirement program with Mutual of New York. The three trustees of APA Retirement Plans will be retained until the trust is dissolved (Bd., Dec. '76).

9. Voted reluctantly to approve the new professional liability insurance rates as reported necessary by the Committee on Member Insurance and Retirement Plans and approved establishment of a policy that a member with two chargeable losses within a three-year period become subject to individual underwriting by the company during the surcharge period, with the provision of appeal to the Loss Control Committee (Bd., Dec. '76).

10. Approved a program feature regarding eligibility for insurance rate deviation for psychiatrists who work full-time (35 hours minimum) in an institution and who want to accept private patients in their off-duty hours (Bd., Apr. '77).

LEGAL MATTERS

1. Referred the issue of *Bartley v. Kremens* to the Commission on Judicial Action for preparation of an amicus curiae brief (Bd., Apr. '76); authorized the Commission on Judicial Action to negotiate with the Mental Health Law Project toward a mutually acceptable position for a joint brief in the case of *Bartley v. Kremens*, regarding voluntary admission of children to psychiatric facilities (Bd., May '76).

2. Authorized increasing the budget expenditure in the *Bartley v. Kremens* case from $10,000 to $15,000 to enable APA to submit its own brief (Bd., June '76).

3. Agreed that APA not sign the Texas District Branch amicus curiae brief (Bd., Apr. '76); authorized the Commission on Judicial Action to find some effective way to collaborate in a limited way as amicus in an appeal of the capital punishment statute in Texas, as outlined by the Commission (Bd., Dec. '76).

4. Approved participation with the Mental Health Law Project in a brief against the required reporting of all patients for whom Schedule II drugs are prescribed, as being a law that might cause undue stigmatization to the patient (*Whalen v. Roe*) (Bd., June '76).

5. Approved the recommendation of the Commission on Judicial Action that the Association not pay for legal briefs written by anyone other than the Commission (Bd., June '76).

6. Ratified the President's emergency action to retain the law firm of Bregman, Abell, Solter, and Kay for a fee of $5,000 to study the matter of the petition by the Association for Advancement of Psychology to the Federal Trade Commission for investigation of the Joint Commission on Accreditation of Hospitals and the American Medical Association in regard to violation of antitrust laws (Ex.C., Sept. '76).

7. Instructed the Budget Committee to consider the allocation in the 1978 budget of $30,000 to the Commission on Judicial Action to be used exclusively to assist district branches to implement judicial actions originating in local areas but having national significance (Bd., Dec. '76).

8. Approved the decision of the Commission on Judicial Action not to participate in the amicus curiae brief of the Mental Health Law Project in the case of *Memel v. Mundy* (Wisconsin) in which allegations are that due process rights of persons appearing for involuntary commitment hearings were violated and that the proper procedures for following the adversary rules were not followed (Bd., Dec. '76).

9. Approved the decision of the Commission on Judicial Action to write a brief to urge the Supreme Court to grant certiorari in the appeal of the Caesar contempt citation, in an effort to direct the attention of the court and the public to the importance of confidentiality (Bd., Dec. '76).

LEGISLATIVE LIAISON

1. Advised the Joint Commission on Government Relations to reword their proposed legislative guidelines to state them positively (Bd., Apr. '76); endorsed the 10 policy recommendations of the Joint Commission on Government Relations as guidelines for legislative representatives and APA to use in legislative and other negotiations, with the proviso that if any one of them is objected to by the Assembly it shall be reconsidered (Bd., June '76); received the Assembly's endorsement of the guidelines (Bd., Dec. '76).

2. Asked the assistance of the Joint Commission on Government Relations in offering APA cooperation in future leg-

islative investigations such as that recently conducted by the Select Committee on Aging (Ex.C., Sept. '76).

3. Authorized the President to write to the Director of the National Insitute of Mental Health requesting an opportunity for APA to review the "Mental Health Legislative Guide" developed by the Mental Health Law Project for NIMH in terms of its impact on the provision of mental health care, in order to express criticisms and make alternative suggestions before its publication (Ex.C., Sept. '76).

4. Ratified the President's emergency action, taken at the request of the Assembly and in collaboration with the Medical Director and the Speaker, to protest the issuance of Executive Order No. 10.1 by the Governor of New York to limit or prohibit psychiatrists in the New York State system from engaging in private practice outside their working hours in state employment (Bd., Dec. '76).

5. Approved publication of *Psychiatry Reports*, a quarterly newsletter for members of Congress (Ex.C., Feb. '77).

6. Ratified the emergency action taken by the APA President on January 10, 1977, on the recommendation of the Council on Mental Health Services with the concurrence of the Medical Director and the Speaker-Elect of the Assembly (acting in the absence of the Speaker), to send the following mailgram to the Secretary of DHEW: "Regarding Public Law 94-484, Title VI—Foreign Medical Graduates. Urge you delay implementation of limitations on foreign medical graduates entering the United States pending further study of impact on delivery of essential services to the mentally disabled. To avoid a serious disruption in service delivery, logic would dictate a gradual phase-in over several years. Furthermore, we urge that the Educational Commission for Foreign Medical Graduates examination be allowed to temporarily substitute for national boards until such time as a suitable examination is prepared and is available overseas. We also urge that instructions be issued allowing a liberal interpretation of waiver provision of the law" (Ex.C., Feb. '77).

7. Asked Mr. Joel Klein, APA Special Counsel, to prepare a procedural format for district branches as general guidelines on how to avoid incurring liability in the course of ethical investigations (Ex.C., Feb. '77).

LIAISON WITH OTHER ORGANIZATIONS

1. Approved the recommendations of the Ad Hoc Committee on the Referenda on Psychiatric Certification for establishment of a new component to facilitate communication between APA and the ABPN (Bd., Dec. '76).

2. Approved submitting three names to the ABPN, with identification given this year by rank order, from which the final selection of the Director will be made (Bd., May '76).

3. Approved a change in the By-Laws of the Inter-American Council of Psychiatric Associations, to allow for greater flexibility in the timing for succession in the post of Secretary-Treasurer; authorized support for the Inter-American Council of Psychiatric Associations for another three years at the rate of $1,200 per year (Bd., May '76).

4. Reaffirmed strongly its conviction that the treatment of psychiatric patients within a hospital setting must be under the supervision of a physician; affirmed that in the interests of total patient care, APA is prepared to take whatever legislative and judicial actions are necessary to implement this (Bd., June '76).

5. Formally requested the Council on Mental Health Services to discuss APA's relationships with other mental health professionals and policy in dealing with them and to formulate concepts and recommendations by which the Association can promote the best interests of the patient (Bd., June '76).

6. After further discussion of the already unwieldly size of the Accreditation Council for Psychiatric Facilities and the belief that only organizations that represent types of services different from the ones currently represented should be admitted, took a stand against further enlargement of the Council (Ex.C., Sept. '76).

7. Approved continuing the current liaison with the National Institute on Alcohol Abuse and Alcoholism; accepted Dr. Auerback's resignation with thanks, and asked the President to appoint a member residing closer to Washington, D.C. (Bd., June '76).

8. Asked the President to delegate a representative to attend the September 27 meeting of the Council on Clinical Classification; asked that the Chairman of the Task Force on Nomenclature and Statistics be invited to the December meeting of the Board for discussion of this issue; and deferred action on cosponsorship until then (Ex.C., Sept. '76).

9. Accepted the invitation to join with the American Academy of Pediatrics, the American College of Obstetricians and Gynecologists, the American College of Physicians, the American College of Surgeons, and the Commission on Professional and Hospital Activities in sponsorship of the Council on Clinical Classifications (Bd., Dec. '76).

10. Approved APA's supporting the statement of the American Medical Association decrying violence on TV (Ex.C., Sept. '76).

11. Deferred action on support for the Council of Medical Specialty Societies (Ex.C., Sept. '76) until December and requested that Dr. Richard Wilbur, Executive Director of the CMSS, be invited to submit a report and be present for the discussion; approved increased dues payment by APA to the CMSS (Bd., Dec. '76).

12. Agreed that the answers to questions asked of APA's prospective nominees to the American Board of Psychiatry and Neurology, Inc., should be regarded as confidential (Ex.C., Sept. '76)

13. Approved a proposal that the American Psychiatric Association become an affiliate member of the Committee on Problems of Drug Dependence (CPDD), in order to gain a voice in matters pertaining to drug abuse, give needed scientific support to a unique evaluation activity (the search for nondependence-producing analgesic drugs), without incurring financial obligation (Bd., Dec. '76).

14. Approved a recommendation of the Committee on Liaison with the American Hospital Association that APA endorse efforts of the JCAH to reorganize itself, develop core standards, and train generalist surveyors (Bd., Dec. '76).

15. Approved appointment by APA's President of a liaison representative to the American Nurses' Association (Bd., Dec. '76).

16. Approved continued liaison with the National Consortium for Child Mental Health Services, with the liaison representative to report to the new Council on Children, Adolescents, and Their Families (Bd., Dec. '76).

17. Received suggestions for coordinating activities to determine how APA or individual members will respond to Federal Trade Commission questions concerning the Joint Commission on Accreditation of Hospitals and other medical organizations, and asked that members keep the Medical Director informed; Mr. Stanley Bregman (APA's attorney in this matter) will comment on the feasibility of designated groups and individuals contacting the FTC directly and pro-

viding that agency with information (Ex.C., Feb. '77).

18. Deferred until April a decision on a recommendation to reappoint the ABPN Director; since two issues were involved (this reappointment and policy for similar future situations), it was deemed a matter for the entire Board of Trustees to decide (Ex.C., Feb. '77).

19. Favored in principle supporting the application of the American Board of Qualification in Electroencephalography (ABQEEG) to the American Board of Psychiatry and Neurology for the establishment of special certification of competency; accepted the recommendation of the Council on Medical Education and Career Development that APA support is made with the proviso that the EEG groups coordinate their activities to eliminate conflicting requests to the ABMS and to ensure that the education and training involved is an addition to basic residency education (Ex.C., Feb. '77).

20. Agreed to lend the name of the American Psychiatric Association as a cosponsor of the 27th Annual Conference on Aging, to be held in Washington, D.C., April 17–20, 1977 (Ex.C., Feb. '77).

21. Approved a contribution of $500 to defray the expense of a newsletter and first seminars for a newly formed Committee for a National Health Policy, which is to serve as a forum for debate and communication around current issues for all sectors of the nation's health care delivery system (Bd., Apr. '77).

22. After hearing a presentation from Dr. John G. Meyer, Quality Assurance Coordinator, CHAMPUS Psychiatric Utilization Review, approved in principle the proposal for a contract between CHAMPUS and the American Psychiatric Association to provide CHAMPUS with a nationwide capability for local/state/regional third-party (psychiatrist) retrospective review of psychiatric services reimbursed or about to be reimbursed by CHAMPUS; authorized the President, the Medical Director, and the Speaker to negotiate a contract (Bd., Apr. '77).

23. Noting that "the quality of his work is outstanding," recommended Dr. Marc Hollender for another 4-year term as APA's nominee to the American Board of Psychiatry and Neurology, Inc. (Bd., Apr. '77).

MEETINGS

1. Received brief progress reports on three APA annual meetings (Toronto, 1977; Atlanta, 1978; San Francisco, 1980); authorized staff to investigate alternate meeting sites for the 1979 meeting if ample facilities are not available in Philadelphia (Bd., Dec. '76).

2. Authorized Meetings Management staff to negotiate for a 1979 city other than New York (Bd., Dec. '76) if the New York Hilton cannot vacate its meeting and exhibit space for the APA annual meeting (Bd., Feb. '77).

3. Approved Chicago as the site of the 1979 APA annual meeting, subject to satisfactory site investigation by Meetings Management staff; and authorized staff to investigate moving either the 1982 or 1983 meeting from the East to the Midwest or Southwest to reestablish the normal rotation pattern for APA meetings (Bd., Apr. '77).

4. Approved recommendations to discontinue the post-opening session reception at the annual meeting and hold a reception following the Convocation; to discontinue organized professional tours as part of the official program; and to change the "Policy and Procedural Manual for Annual Meetings" concerning selection of the Grand Marshal and Marshal for the Convocation, meetings of councils and components held during the annual meeting, and prohibition of sales on the exhibit floor or any official area of the convention (to comply with new IRS regulations) (Bd., Dec. '76).

5. Authorized seeking outside funds to support a steering committee that will plan a Conference on Expressive Arts Therapies, to be held in 1977 (Bd., Dec. '76); heard preliminary plans for a conference to bring together representatives from various expressive arts therapies, with a general goal to identify, explore, and seek solutions to problems that confront in varying degrees the associations and practitioners in these therapies (Bd., Apr. '77).

6. Authorized the Ad Hoc Committee To Plan a Conference on the Chronic Mental Patients to seek funds for a conference (Ex.C., Feb. '77).

MEMBERSHIP MATTERS

1. Recommended to the APA Membership Committee and the Assembly Membership Committee that all noncitizen members and Fellows of the APA be granted a suitable dues differential in recognition of the fact that a part of their dues is spent for matters of concern to U.S. residents only; requested that the two Membership Committees meet together and report their recommendations (Ex.C., Sept. '76).

2. Approved the conjoint Membership Committees' recommendation that dues shall be reduced for noncitizens of the United States who live outside the borders of the United States and left determination of the dollar amount to the Treasurer and appropriate committees or individuals (Bd., Dec. '76).

3. Tabled a motion for a procedural change to establish a waiver of dues for those members who have achieved age 70 and have been dues-paying members for the requisite number of years but have *not* achieved Life Fellow status, and a decision whether they should pay for journals and other services (until the fiscal implications have been explored) (Bd., Dec. '76).

4. Deferred all other policy actions regarding dues status of Life Members and Life Fellows and whether publications should be paid for after dues payment ceases; whether Inactive Members should pay publication costs; whether there should be a new category of Life Associate Member; what the length of time should be for eligibility for Fellow status (until fiscal implications of these proposals are determined) (Bd., Dec. '76).

5. Requested the Committee on Constitution and By-Laws and the Assembly to explore the issue of district branch involvement in legislative matters and whether a member who refuses to pay assessments for such activity can be dropped from the district branch (Ex.C., Sept. '76).

6. Approved the opinion of the Committee on Constitution and By-Laws that: "Even if a substantial portion of the budget of a district branch is spent on legislative matters, the district branch is not necessarily in violation of the APA Constitution. The committee believes that this depends on what the legislative matters are and whether the activities carried on are propaganda or the influencing of legislation. Legislative matters are not necessarily propaganda, lobbying, and/or attempting to influence legislation. However, they may be considered so if they fall outside the objectives of the Association, stated, in part, as follows: to advance the standards of all psychiatric services and facilities; to foster

cooperation of all concerned with medical, psychological, social and legal aspects of mental health and illness; to make psychiatric knowledge available to other practitioners of medicine, to scientists in other fields of knowledge, and to the public. Therefore, if a district branch spends a substantial portion of its budget on legislative matters, this is not necessarily a violation of Article II, Section 2 of the APA Constitution; the question of violation depends on exactly what the 'legislative matters' consist of" (Bd., Dec. '76).

7. After deferring action for several meetings until further information and legal opinion could be obtained regarding one APA member who had paid national dues and part of district branch dues but withheld payment of a district branch assessment because of his objection to lobbying activities, reluctantly dropped the member from APA because he had been dropped by the district branch (Ex.C., Feb. '77). Noting Chapter Eight, Section 7, of the By-Laws and that proper recourse is appeal through the Recorder to the Assembly, ratified the February 19, 1977, dropping action of the Executive Committee: a member dropped by the district branch can no longer remain a member of APA (Bd., Apr. '77).

8. Referred study of the issues revealed by the protest membership case reported above to the Committee on Constitution and By-Laws for its recommendations, to the Membership Committee for information, and to the Joint Conference Committee on Key Conference Recommendations for a mechanism for the future (Bd., Apr. '77).

POSITION STATEMENTS AND RESOLUTIONS

1. Supported the Area V action paper deploring the use of mental hospitals as prisons, and asked that information be published in *Psychiatric News* about the Florida law recently enacted and the APA position that a hospital used to treat the mentally ill should not be used as a facility to house prisoners who are not there to receive treatment (Bd., June '76).

2. Authorized the Medical Director to convey to the Social Security Administration the Board's protest of current Medicare policy in regard to weekend passes, expressing alarm over the loss of this important therapeutic modality (Bd., June '76).

3. Withheld approval for publication of the statement on meditation, until action by the Assembly (Bd., June '76); approved the "Position Statement on Meditation," as recommended by the Council on Research and Development and approved by the Reference Committee and the Assembly (Ex.C., Feb. '77).

4. At the request of the National Association on Veterans Administration Physicians, approved in principle the recommendations of the Committee on Federal Government Health Services to support Articles VII and XI of their National Program, regarding the "denial of the due process afforded other Federal employees" and the "physician-administrative relationship" (Ex.C., Feb. '77).

5. Approved a policy statement of the Ethics Committee: "The Ethics Committee opposes release of any information relative to deliberations on ethics matters other than to national officers and members of the Board of Trustees." (Bd., Dec. '76).

6. Approved in principle the proposed statement on "The Crisis in Psychiatric Manpower: Toward a National Psychiatric Manpower Policy," to be sent to the Council on Medical Education and Career Development for presentation at the next meeting of the National Advisory Mental Health Council (Bd., Dec. '76).

7. Approved restating APA's positions of 1971 and 1972 regarding abuse of psychiatric facilities and procedures, and approved the final form of a new statement for submission to the World Psychiatric Association for action: "Proposal of the American Psychiatric Association to the World Psychiatric Association regarding Abuse of Psychiatric Procedures" (Ex. C., Sept. '76).

8. With concern about the World Psychiatric Association Declaration of Hawaii, voted that no representative of APA be permitted to support the canons of ethics of the World Psychiatric Association as now written and that they be instructed to oppose the draft of the Declaration of Hawaii until modifications have been made in the part dealing with detention aspects and the provisions for exceptions to confidentiality (Bd., Dec. '76); after deferring action to allow time for suggested revisions, accepted the World Psychiatric Association Declaration of Hawaii, in principle, and asked that it be transmitted to the World Psychiatric Association Secretary-General with the recommended changes of the APA Ethics Committee and the Board (Bd., Apr. '77).

10. Noting the need for a similar document for the United States, asked the Ethics Committee to draft a statement in regard to ethical considerations for psychiatrist-patient relationships, taking into account institutional relationships, with special input requested from the California Psychiatric Associations about their experiences (Bd., Apr. '77).

11. Once this statement is adopted in principle and forwarded to the WPA, approved publicizing the full content of the statement approved by this Board, with the notation that it is subject to revision by the WPA (Bd., Apr. '77).

12. Approved publication of the *Manual on Peer Review* as a resource document for the district branches and others; general modifications and local adaptations may be required (Bd., June '76).

13. Authorized publication of the "Position Statement on Support for Psychiatric Research," the "Position Statement on the Right to Adequate Care and Treatment for the Mentally Ill and Mentally Retarded" and the "Position Statement on Rehabilitation," approved by the Assembly (Bd., Dec. '76).

14. Authorized publication of *Intervening in Community Crises: An Introduction for Psychiatrists*, together with the material developed from responses to a questionnaire included in the original report (Bd., Dec. '76).

15. Approved the manuscript, "As the Nation Moves Toward National Health Insurance, What About the Mentally Ill?" for publication (Ex. C., Feb. '77).

16. Authorized publication of the "Position Statement on the Problem-Oriented Record-Keeping System," the policy portions of which had previously been approved by the Assembly and the Board (Bd., Apr. '77).

JULES H. MASSERMAN, M.D.

Report of the Treasurer

GENERAL: This report is prepared from audited figures for the fiscal period that ended December 31,1976. Data presented here also appear in the auditor's annual report.

Attached hereto is a statement of financial condition (table 1) and pie charts (figures 1 and 2) reflecting revenues earned and functional costs for the fiscal period. This report, together with the statement and charts, will provide the membership with the information they need to assess the operation and financial condition of the Association.

CHANGE IN FISCAL YEAR: APA received authorization from the Internal Revenue Service to change its fiscal year from April 1–March 31 to a calendar year, effective January 1, 1977. It was therefore necessary to terminate the 1976–1977 fiscal year on December 31, 1976, leading to a 9-month fiscal period (from April 1, 1976, through December 31, 1976). It should be noted that in figures 1 and 2 the comparison of functional costs for the 9-month period for 1976 and for the 12-month period for fiscal year 1975–1976 is not significantly affected by the dissimilarity of fiscal periods. However, the comparison of functional revenue is distorted since revenue from advertising, subscriptions, and book sales for a 9-month period in 1976 is contrasted with full annual membership dues and annual meeting receipts. In addition, this report does not discuss the relationship between actual income and expenditures and related budget figures, since the 12-month budget projections cannot be reasonably compared with budget execution covering the 9-month fiscal period for 1976.

INCOME AND EXPENDITURES: The change in the APA fiscal year, combined with unanticipated budget economies, resulted in income from operations of $5,067,226, compared to expenses of $4,233,522, for a surplus of $833,704. Of this amount, $579,075 has been placed in a reserve account and will be used to offset a portion of the costs of operations during 1977, 1978, and 1979. These funds should preclude the need for a dues increase during this 3-year period. The remainder of the surplus, $254,629, has been placed in a reserve for future expansion and development.

Operations of the Board of Trustees, the Councils, and the Assembly accounted for 18.6% of the expenditures, about the same as for the prior year. Public Affairs required 4.82% of the expenditures, and administrative costs amounted to 10.09%, each up less than one half of one percent.

Member services accounted for 26.78% of the budget, an increase of 3.5%, due primarily to a stronger emphasis on continuing education and other direct services to members. Publications costs amounted to 39.7% for a decrease of 4.59%. This savings stems primarily from renegotiation of printing contracts and increased grant support for preparation of manuscripts.

EMPLOYEE BENEFITS: APA seeks to maintain salaries approximately commensurate with those paid by the federal government. Therefore, a cost-of-living increase (4.8%) was awarded to our employees in October 1976.

While the employer's contribution toward Social Security taxes remained unchanged, the base amount upon which this tax is calculated increased by 8.5%, resulting in an increased expenditure of approximately $8,000 in this category.

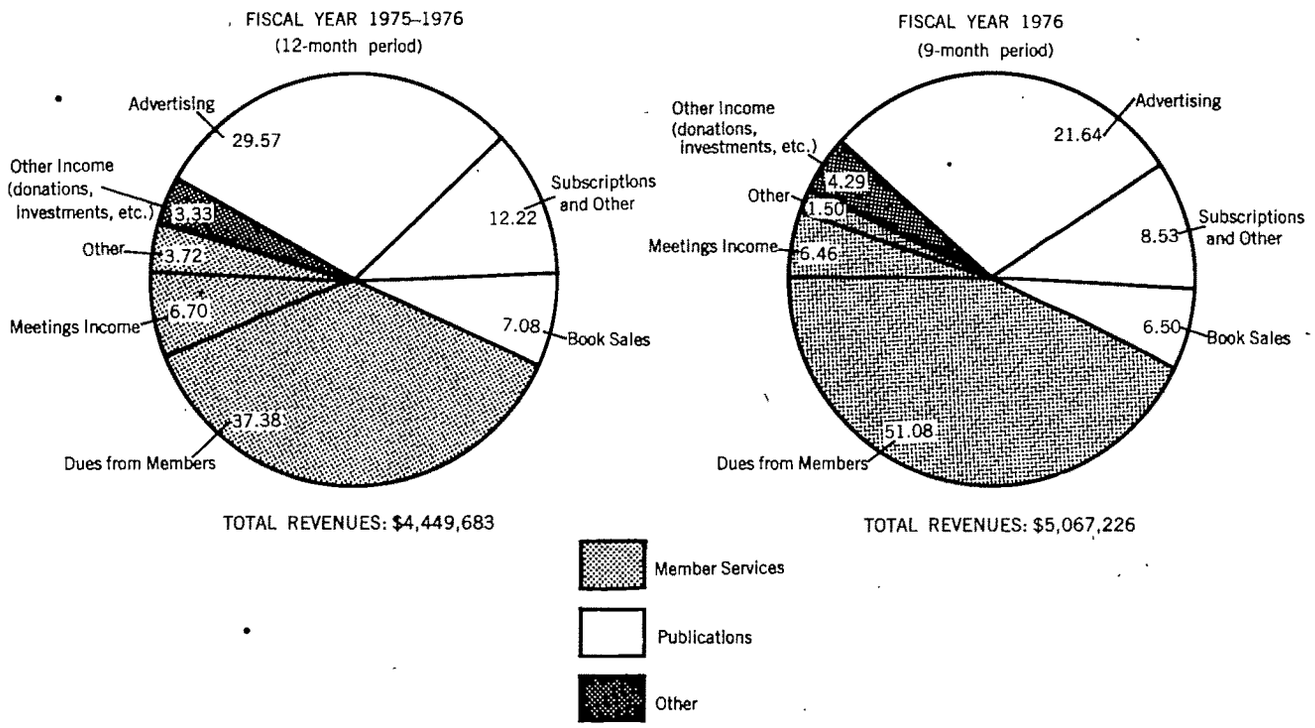
APA's annual contribution to the Employees Retirement Plan was reduced from $116,470 to $76,269 (a savings of $40,201) by changing the method of calculating the payment from a mathematical formula to an actuarial projection by Mutual Life Insurance Company of New York.

TABLE 1
Comparison of Fiscal Years 1976 (9 Months) and 1975–1976 (12 Months)

Item	1976	1975–1976
ASSETS		
Cash	$ 424,057	$ 7,620
Certificates of deposit and savings accounts	320,000	770,000
Accounts receivable	386,312	492,203
Accrued interest receivable	17,041	29,559
Deferred and prepaid expenses	103,501	99,711
Marketable securities		
Stocks and bonds (at quoted market value)	1,024,500	1,023,749
U.S. Treasury bills, etc., short-term investments at cost	1,795,388	594,130
Notes and advances receivable from the American Psychiatric Museum Association, Inc.	1,757,085	1,757,085
Less valuation reserve	(1,757,085)	(1,757,085)
Land and buildings (at nominal value)	1	1
Furniture and equipment (at nominal value)	1	1
Total assets	4,070,801	3,016,974
Deduct		
Cash and marketable securities allocated to restricted funds from general fund	366,260	302,223
Total general fund	$3,704,541	$2,714,751
LIABILITIES		
Accounts payable and accrued expenses	64,689	137,464
Due to district branches	46,052	3,639
Deferred income		
Annual meeting, etc.	122,579	20,563
Advance dues collections	1,787,393	—
Funds collected and held for Trustees of the Benjamin Rush Foundation	684	10
Reserve for stabilization of future dues	—	579,075
Reserve for future expansion and development	1,500,000	1,754,629
Less valuation reserve and marketable securities	(74,584)	(38,357)
Total liabilities	3,446,813	2,457,023
Unrestricted surplus		
At beginning of year	580,917	257,728
Net change during the year ended	(323,189)	—
At end of year	257,728	257,728
Total general fund	3,704,541	2,714,751

This is an edited version of the report presented by the Treasurer to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

FIGURE 1
Comparison of APA Revenues, in Percents



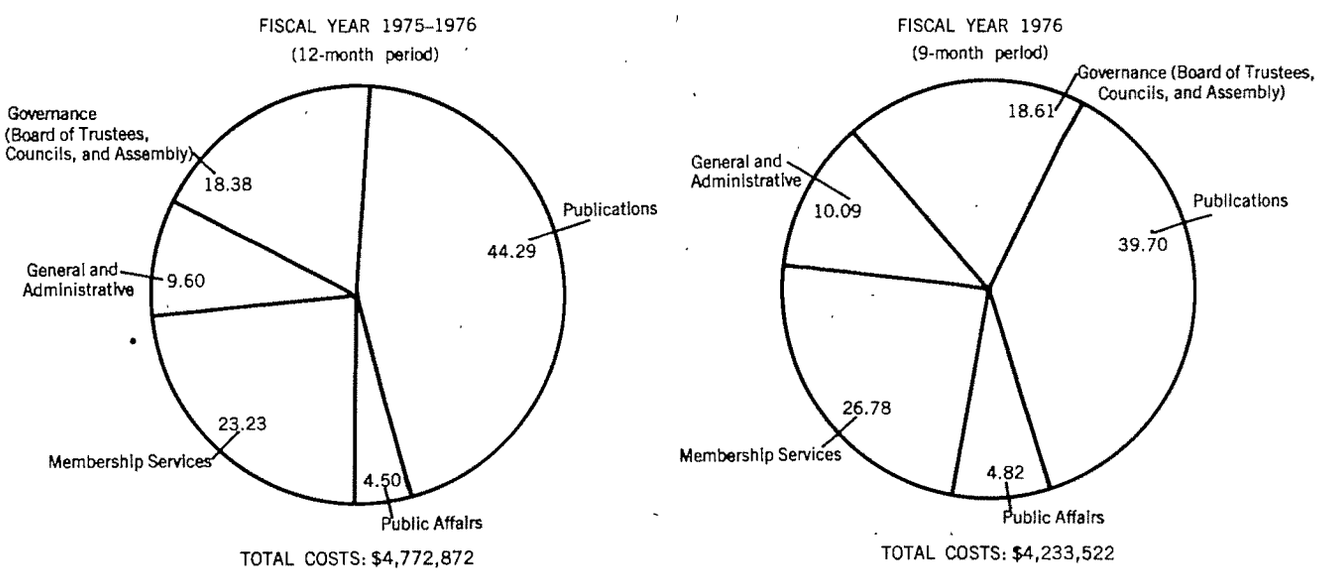


FIGURE 2
Comparison of APA Costs, in Percents

APA was advised by Blue Cross/Blue Shield that the cost of health insurance coverage for staff would increase by 88.7%, or approximately $33,000, per year. Most of this increase related to the major medical portion of the plan. While the Association is maintaining the Blue Cross/Blue Shield basic hospitalization plan, we have selected Mutual Life Insurance Company of New York (MONY) to provide basic surgical coverage and the major medical portion of the plan at an estimated savings to the Association of $20,000 below the proposed Blue Cross/Blue Shield rates. This change also represents considerable savings to a majority of the staff contributing toward their health insurance program.

BUILDING OPERATION AND MAINTENANCE: The trend toward increased costs of building operation and maintenance noted during past years continued during 1976. Costs for the 1976 9-month fiscal period were virtually the same as those

for the preceding 12-month period. Also, the Central Office building currently fails to provide adequate working conditions for staff during warm and cold periods. The situation stems largely from the fact that the heating, cooling, and electrical systems of the Central Office building are reaching the end of their projected life expectancy. This problem, together with other deficiencies related to functional space requirements and structural deterioration, prompted a complete evaluation of the APA buildings by an outside architectural and engineering firm and an analysis of real estate opportunities for APA in the Washington metropolitan area by a real estate consulting group. These studies will provide data necessary for a decision as to whether the Association should undertake a major renovation of its present facilities or purchase new properties in Washington.

INVESTMENTS: The market value of securities in the equities portion of the APA portfolio was $387,058 as of December 23, 1975. The total fund appreciated in market value by $87,139 during 1976 and generated an additional $12,079 in dividends and interest. Total fund earnings for 1976 were $99,218 (25.6%). The fund return was slightly higher than the Standard & Poor's "500" Index and a little lower than the New York Stock Exchange Composite.

The remainder of the portfolio contains intermediate-term and short-term obligations. This fund ranged from a high of $3,166,611 to a low of $1,913,903 during 1976. Intermediate-term bonds accounted for $650,000, earning a 5.42% annual rate of interest. Income from these bonds was $17,275 for the 9-month period. An additional $320,000 invested in savings and loan association certificates earned interest at the rate of 7.5%, for income of $18,000. Late in 1976, $450,000 from maturing government obligations was deposited temporarily in bank savings accounts earning 5% interest because of the unusually low yields available from government obligations at that time. Treasury bills constituted the balance of this fund and varied between $1,850,000 and $300,000 during 1976. Earnings from this portion of the portfolio amounted to approximately $76,500 for the 9-month fiscal period.

PUBLICATIONS: *Psychiatric News* received income of $591,146 contrasted with expenses of $530,868, for a surplus from operations of $60,278. The profit from operations during the 1976 9-month fiscal period represents an increase of almost 100% over 1976 experience, and it is estimated that even greater improvement would have been shown during a 12-month fiscal period. This gain stems primarily from renegotiation of the newspaper's printing contract.

The *American Journal of Psychiatry* produced income of $637,513 and generated expenses of $660,986, for a deficit of $23,473. It should be noted that the Association levies an overhead charge to its three basic publications at the rate established for indirect costs for federal grants and contracts. The overhead rate for the *American Journal of Psychiatry* during 1976 was 28.7% of direct costs. Excluding the APA overhead charge, this publication showed a surplus of $123,926.

Hospital & Community Psychiatry realized income amounting to $200,931 and expenses of $286,290. The resulting deficit was $85,359. After adjusting for the APA overhead charge, the deficit for 1976 was reduced to $21,517, and, on this basis, a surplus is expected for 1977.

The Association maintains approximately 90 publications in inventory. The average monthly sales volume of these publications exceeded that of the previous fiscal year. The Association's publications are produced and marketed at prices that assure a return of the printing and distribution costs. The excess of sales over expenses keeps this activity self-sustaining.

CONCLUSION: I wish to express my gratitude to the membership for entrusting me with the responsibility for the fiscal affairs of APA and to the Assembly of District Branches, the Board of Trustees, the officers, and the Investment Advisory Committee for their support and continuing interest in the financial stability of the Association. Appreciation is also due the Medical Director, the Deputy Director for Business Administration, the Comptroller, and the entire staff for their capable assistance whenever needed during the year.

CHARLES B. WILKINSON, M.D.

Report of the Medical Director

FOR THE PAST several years, I have attempted in my report to the membership to cover the broad issues with which staff has been concerned in implementing Association policies. Although recommendations for increased emphasis and personnel in certain areas have been followed, we have all been concerned with saving our members important dollars and establishing careful methods of accountability.

One of our major efforts last year was an attempt to improve communications with members. This year, I would like to highlight recent changes in the structure and function of the Central Office that we hope will offer members a wider range of services, improve communication, and enable us to deal with the many issues that affect the profession. These changes are a result of recommendations made by the Assembly and authorized by the Board. They do indeed strengthen our capacity to deal with the current challenges to the field.

For historical purposes, I have asked each department and division head, and each Deputy Medical Director, to prepare a detailed report on activities, which is available to any member.

SPECIAL COUNSELS AND DIRECTOR OF GOVERNMENT RELATIONS

On January 1, 1977, Mr. Joel Klein of the law firm of Rogovin, Stern & Huge was appointed APA Special Counsel. He works primarily with the Commission on Judicial Action, but has several additional responsibilities. He has been extremely helpful with advice on the effect of the new IRS regulations (in connection with the Tax Reform Act of 1976) and on the annual meeting in Toronto; he has also worked closely with Mr. Stanley Bregman and Dr. Carolyn B. Robinowitz on the Federal Trade Commission's investigations of medical specialties and the Joint Commission on Accreditation of Hospitals.

In addition, Mr. Klein testified on behalf of the Louisiana Psychiatric Association in Baton Rouge with respect to proposed amendments to the state civil commitment statute. The president of the Louisiana Psychiatric Association, Dr. Robert Newman, indicated that Mr. Klein's assistance "has been very helpful in . . . putting our medical thinking into legal form. His testimony before the legislative subcommittee in Baton Rouge . . . was quite persuasive. He made an excellent case for providing access to treatment for sick people while preserving their civil rights . . . The entire Association is aware of and appreciative of . . . Joel's assistance." Mr. Klein has worked with several other district branches on a number of judicial actions and state concerns.

Joel Klein enhances the ability of the Association and its Central Office to provide legal assistance to members and staff. We are pleased with this new activity and hope that it will become more visible to our membership.

On May 1, 1977, Mr. Jay B. Cutler joined the staff as Special Counsel and Director of Government Relations. Mr. Cutler had served as Minority Counsel and Staff Director for the U.S. Senate Labor and Public Welfare Committee, reporting directly to Senator Jacob K. Javits. He was in charge of organizing and coordinating legislative activities on behalf of the minority (Republican) members of the committee regarding education, labor, health, and public welfare. Prior to this, he was minority counsel for the U.S. Senate Health Subcommittee and Alcoholism and Narcotics Subcommittee. Mr. Cutler has worked on Capitol Hill since 1968.

By adding a staff member possessing the experience and the national stature of Mr. Cutler, the Association is making a significant commitment to be more continuously active in all areas of government affairs. At the annual meeting Mr. Cutler met and talked with the various constituencies within APA to acquaint himself more fully with our membership.

I am particularly grateful to the search committee who aided in the process that led to Mr. Cutler's hiring: Dr. Stanley Yolles, chairperson, Drs. Robert Campbell, Melvin Lipsett, and Johnnie Gallemore, and to the Washington Psychiatric Society members, Dr. George McMahon, president, and Dr. John J. McGrath, chairperson of the Washington Psychiatric Political Action Committee, who aided in interviewing the many candidates for the position.

APA's government relations activities were formalized in 1970 when Mr. Caesar Giolito was added to the staff of the Division on Public Affairs. A separate division was created in 1974 as the Association became more active in legislative affairs. The annual Institutes on Government Operations began in 1972 to provide assistance to the district branches in their legislative efforts; the Sixth Institute held in March this year was attended by 135 legislative representatives and district branch representatives. A highlight of this Institute was a "first" briefing at the White House.

The creation of the Joint Commission on Government Relations allowed a two-way communication mechanism—between the Board and the Assembly—with continuity and guidelines as to the Association's position on various items of legislation. In addition, this commission has formed a Legislative Review Committee to review pertinent federal legislation and interpret legislation vis-à-vis APA policy and the 10 legislative guidelines approved by the Trustees and the Assembly.

In the coming year we plan to become more involved in the state legislative field. The Division of Government Relations already publishes *State Legislative Update*, reporting current developments in various states, and we anticipate the capacity to be of greater assistance in the state legislative process.

An additional publication (a joint effort of the Joint Commission on Government Relations and the Joint Commission on Public Affairs), *Psychiatry Reports*, is a special newsletter aimed at members of Congress that focuses on psychiatric issues and legislation.

This is an edited version of the report presented by the Medical Director to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

LEGAL AND LEGISLATIVE REPRESENTATIVE

Beginning in 1976 the Association entered into a limited agreement with Mr. Stanley I. Bregman of the law firm of Bregman, Abel, Solter and Kay to participate in such activities (on a part-time basis) as the Institute on Government Operations and the meetings of the Joint Commission on Government Relations. In addition Mr. Bregman assists with selected legislative issues and passes on information of interest to APA. He administratively relates to Dr. D.W. Hammersly. Mr. Bregman serves as consultant to the newly formed Legislative Review Committee (within the framework of the Joint Commission on Government Relations).

In late 1976, Mr. Bregman called our attention to the fact that the Association for the Advancement of Psychology had filed a memorandum with the FTC alleging violation of the antitrust laws by the Joint Commission on Accreditation of Hospitals and/or the AMA. Mr. Bregman assisted in preparing APA's response to this memorandum and continues to follow this case. In addition he has helped various APA members to provide information on an individual basis to the FTC.

PUBLIC AFFAIRS

In the fall of 1976 the Association expanded its Division of Public Affairs to include Mr. Ronald McMillen as Assistant Director, working with Mr. Robert L. Robinson, Director. In addition, a new Joint Commission on Public Affairs was established with Dr. Shervert Frazier as chairperson. The new commission and the availability of Mr. McMillen have increased activities aimed at achieving the Association's commitment to full and open communication with the public. The division prepared "Guidelines for Psychiatrists Working with the Communications Media," which should be helpful during a period when many of our members are being called to comment in the press, on radio, or on television.

The division also worked closely with the APA Committee on Financing Mental Health Care in the publication of "As The Nation Moves Toward National Health Insurance, What About the Mentally Ill?"

The Joint Commission on Public Affairs has been actively planning a study of public attitudes toward psychiatry, which should begin during 1977–1978.

In general, our relations with the media have been improving during this past year. Significant numbers of antipsychiatric viewpoints, however, continue to be presented in the major media, and we need to be quite active in anticipating as well as responding to these criticisms. The staff will be working closely with the Joint Commission on Public Affairs to advocate a fair presentation of psychiatry.

PEER REVIEW—CONSULTANT PROGRAM

To facilitate the activities of district branches in peer review programs, APA hired Dr. Richard Dorsey as a consultant to visit peer review committees, district branches, general members, and insurers. In 1976 Dr. Dorsey visited 32 district branches to explain peer review and APA's policy of seeking financing and review within the same framework as the rest of medicine and parity for psychiatry with other medical specialties.

With the Association's current emphasis on peer review, insurance, and government relations, the Field Consultant program probably will be continued for an additional year. Dr. Dorsey has provided leadership in making it possible for psychiatric peer review to develop rapidly over the next few years; in this regard psychiatry is in the forefront of medical specialties.

This has been a successful "how to do it" project, done at minimum cost, that has provided valuable information to our members and may be a model for similar activities.

EDUCATION

Under the direction of Dr. Carolyn B. Robinowitz, Deputy Medical Director, major changes have taken place in the structure and function of the Office of Education since September 1976. This office now has responsibility for all educational efforts within APA—undergraduate, graduate, and continuing education. A full-time staff has helped to achieve coordinating and leadership functions in continuing education not previously possible. Some 200 programs for continuing medical education were approved and cosponsored by APA through the Office of Education.

The Board and Assembly also approved the guidelines for continuing medical education. In 1974 the membership voted to approve an amendment to the By-Laws requiring participation in continuing education as a requisite for maintaining APA membership in good standing. The program began operation in July 1976; July 1979 is the final date for first reporting.

Dr. Robinowitz will continue her meetings with district branch committees on education and continuing education. In the past 8 months, she has visited Louisiana, Northern California, Washington, Georgia, Connecticut, and Manhattan/Bronx; she attended the Area II divisional meeting where she met with the committee chairpersons from New York State.

The Office of Education has also worked to establish liaison with other psychiatric education and service organizations. Dr. Robinowitz, on behalf of APA, has acted to convene various groups to deal with such emerging problems as the regulations for P.L. 94-484 (Health Manpower), the NIMH budget, the NIMH Forward Plan, etc. The Association has moved from a reactive stance to a more proactive one.

In September 1977 Suzanne Quick reported for duty as the Assistant Director of the Office of Education, and it is anticipated that she will assume major responsibility for the self-assessment test and preparation of evaluation and assessment studies concerning the continuing education activities.

MEMBER BENEFITS

During the Assembly meeting in October, we proposed an Office of Member Benefits. In addition to handling staff responsibility for the five major insurance benefit plans offered to members (professional liability, major medical, disability income and professional overhead expense, family group term life insurance, pension plans), this office will be concerned with continuously reviewing existing insurance programs in light of the needs of APA members; handling all member inquiries and complaints concerning these insurance programs, and coordinating member benefit programs with district branches.

We hope to make this office a focal point for inquiries from

members concerning perquisites and benefits of membership in the Association. We have hired a Director of the Office of Member Benefits, Mr. Thomas J. Yeakle, who began work just before the annual meeting. Mr. Yeakle was formerly with Mutual of New York in various positions, including Mass Marketing Manager and Regional Director of Group and Pension Sales. He has experience in the design, development, sale, implementation, and service of pensions and profit sharing, annuity programs, life insurance programs, major medical insurance, etc. He is familiar with professional liability insurance programs as well. We believe that Mr. Yeakle will be a problem solver who can communicate effectively with our members and improve the Central Office's ability to deal with the membership vis-à-vis member benefits.

There is a keen awareness of the members' concerns over the malpractice crisis, and we are pleased with the leadership of Dr. Chester Trent and the various insurance committees. The Committee on Member Professional Liability Insurance has been exploring the possibility of APA's establishing or purchasing its own professional liability insurance company and will offer its recommendations at a later date.

For the first time, the liability insurance carrier appears to want to negotiate, and the company is considering a plan that will allow partial payment on a malpractice policy for those who work in institutions (which have malpractice insurance on employees) and have some private outside practice.

ASSEMBLY—BOARD OF TRUSTEES

Staff has attempted to facilitate problem-solving in the complex governance of APA with the creation of a position in the Central Office of Coordinator, Assembly and Board of Trustees. Working out of the Medical Director's Office and under the supervision of a Deputy Medical Director, this person will coordinate the secretarial and clerical activities of the Assembly of District Branch Office and the Board of Trustees and will implement policy approved by the Assembly and the Board. We believe that this will facilitate deliberation on action papers, including coordination of consideration by multiple bodies within the Association.

ANNUAL MEETING

As the programming and staffing responsibilities become more complex for the annual meeting (continuing education courses, Category 1 CME credit for the program, etc.), a need arose for staff coordination and the creation of a Staff Committee on the Annual Meeting, ably chaired by Dr. Henry H. Work. With increased communication among staff members who have responsibility for different aspects of the program and social and management aspects of the meeting, we plan to integrate the entire operation from the staff point of view.

We have enjoyed working with Dr. Peter Martin in his role as chairperson of the Program Committee for the past several years and commend him for the excellent innovations that he has brought to the annual meeting program. Dr. Allan Beigel is now the Program Committee chairperson, and the staff looks forward to continued cooperation with the Program and Annual Meeting Committees.

BUSINESS ADMINISTRATION

The second year of operation for this office has now been completed. During the first year of operation, there was a reorganization of the business activities, a balanced budget was presented and approved, and the APA investment portfolio was brought under tighter control. Emphasis during the second year centered on the implementation, expansion, and improvement of programs, development of a personnel classification system, replenishment of reserves to offset deficits from prior years, the establishment of an operating reserve to preclude the need for a dues increase, and a survey of the APA buildings in terms of the feasibility of renovating the existing properties or purchasing other property.

I have been extremely pleased with the excellent leadership of Dr. John Visher as chairperson of the Budget Committee and the increased cooperation among the staff, the Budget Committee, and the Treasurer, Dr. Charles Wilkinson, with the goal of greater fiscal soundness for the Association.

The Investment Advisory Committee, composed of eminent financiers in Washington, D.C. (Dr. Frederick Amling, chairperson, Mr. F. Elwood Davis, and Mr. Hilleary F. Hoskinson) completed its initial review and recommendations on our investments, and the Budget Committee reports that it is very favorably impressed with the present status of our investments and the professional management and advice the Association is now receiving.

This year also marked IRS approval for a change in the APA fiscal year, from April 1–March 31 to a calendar year. Formal approval, received in March 1977, made it possible to initiate the new fiscal year on a retroactive basis to January 1, 1977.

I personally wish to commend Dr. Jack White for his initiative in many areas of the administration of the Association's finances, and the excellent supervision provided to the various departments under his aegis. Our fiscal well-being and the administration thereof have improved immeasurably under his skillful leadership.

CHILD PSYCHIATRY, MINORITY AFFAIRS, AND WOMEN IN PSYCHIATRY

The responsibilities of Dr. Jeanne Spurlock and her staff have increased considerably as a result of the establishment of the Council on Children, Adolescents, and Their Families. This office also provides staff support to the Council on National Affairs.

Work continues on the research project funded by the Falk Medical Fund. "Identification of Strengths in Minority Group Families with a Disturbed/Disturbing Child," a book-length discussion including a literature review and an evaluation of case studies, is near completion.

Additional funding will be required to continue the APA/NIMH Fellowship Program. To date, 38 Fellowships have been awarded and this program has provided an important experience for minority psychiatrists. Before the 1976 Fall Committee Meetings, a research symposium was held that provided a great deal of useful information about research in minority problems.

PUBLICATIONS

The successful scientific journal, the *American Journal of*

Psychiatry, continues its excellent quality, largely because of the efforts of its Editor for the past 12 years, Dr. Francis J. Braceland, and its highly competent staff.

Dr. Braceland asked Dr. Robert W. Gibson to appoint a search committee for a new editor of the *Journal*. The transfer will be slow and with all due deliberation; Dr. Braceland has indicated that he hopes a new editor will be on board by July 1, 1978.

The Association salutes Dr. Braceland for bringing the *American Journal of Psychiatry* into the vanguard of psychiatric journals all over the world. The *Journal* is in excellent shape, and Dr. Braceland deserves the credit for a brilliant period of stewardship.

In the fall, the Council on Internal Organization met with staff and recommended that a committee be established to review and coordinate the functions of the Hospital & Community Psychiatry Service, Institute, and journal.

Largely under the influence of the Editor, Dr. Donald W. Hammersley, and the Managing Editor, Ms. Teddye Clayton, the journal *Hospital & Community Psychiatry* has brought income and expenses into closer alignment; this move toward fiscal accountability is to be commended. The editorial content continues to provide practical, relevant information for psychiatrists and other mental health professionals working in institutional and agency settings. The July 1976 Bicentennial issue of *Hospital & Community Psychiatry*, a remarkable historical account of mental health care in America, was promoted in *Psychiatric News* and some 350 additional copies were sold.

The 1977 Hospital & Community Psychiatry Institute will be held in San Francisco in October and the theme, "The Chronic Patient: Rights, Responsibilities and Resources," ties into the major conference being planned on this topic; it will also provide important data as the President's Commission on Mental Health makes its recommendations concerning delivery of mental health services. We hope to work closely with the commission and their staff; several staff components will be involved in the effort to provide information.

In January 1977 *Psychiatric News* celebrated its 11th birthday and continues to be one of the most widely read publications in the field of psychiatry. I join Mr. Robert L. Robinson, Editor, and Mr. Herbert Gant, Managing Editor, and their staff in being pleased with the appointment of an ad hoc committee (Dr. John Nemiah, chairperson, Drs. Zigmond Lebensohn, and John Visher) to review the newspaper. The newspaper staff has had increased interaction with the membership, with special attention to the needs of minority group psychiatrists, residents, and continuing education activities of the Association. The quality of journalism is high as the paper continues to report news of wide interest and concern to our members.

JOINT INFORMATION SERVICE

Mr. Raymond M. Glasscote and his staff are to be commended for their continued productivity. Two important books were published this year—*Old Folks at Homes* and *Sixteen Indices*. In press and expected by the end of 1977 are two timely studies, one on comprehensive community-based mental health services for the elderly here and in Europe, and a second on primary prevention activities in community mental health centers.

VI WORLD CONGRESS OF PSYCHIATRY

The Association was host to this meeting in Hawaii in August 1977 and provided staff and office space. Activities increased as deadlines for submission of final abstracts approached. The final program and the book of abstracts were distributed to all participants at the time of registration.

INSURANCE

Ms. Evelyn Myers, in addition to her duties as Managing Editor of the *American Journal of Psychiatry*, continues to be our "resident" insurance consultant. Ms. Myers spent a great deal of time working with the Committee on Financing Mental Health Care in the production of APA's new pamphlet, "As the Nation Moves Toward National Health Insurance, What About the Mentally Ill?" This is now available from APA and contains the Principles of Psychiatric Coverage Under National Health Insurance, approved by the Trustees and the Assembly.

Since it has become increasingly clear that the staff must have additional resources to collect necessary data to reinforce our case in Congress on utilization and costs of mental health benefits, we plan to hire a consulting health economist to continue the work of the late Dr. Louis Reed. In addition, it is our intent to have the insurance consultant design health/mental health interface studies that take a closer look at the potential cost savings in general health care when psychiatric care is delivered.

COMPREHENSIVE HEALTH PLANNING

Under Dr. Hammersley's administrative aegis, Mr. Irvin Muszynski has served as Administrative Assistant, and for the past year has continued efforts to secure psychiatric input to the national health planning structure established by P.L. 93-641. An orientation packet on this law was prepared for the district branches and is available on request. To date, 42 district branches have designated specific contacts to act in a liaison capacity with the Committee and Office of Comprehensive Health Planning.

Mr. Muszynski has also been designated APA's Liaison Officer for Federal Agency Affairs; his responsibilities will include additional activities with federal agencies responsible for the administration of programs that affect psychiatry and mental health care in general. To date, this office has responded to issues that include proposed revisions by the Social Security Administration concerning disclosures of physicians' names and medical information to third parties, proposed regulations by the Office of Education for handicapped children, etc. This office is also working closely with the APA Office of Education to ensure timely and substantive responses to the various issues presented by regulations to implement P.L. 94-484, Health Professions Education Assistance Act of 1976. Information on this law and its implementation has been circulated to each district branch.

MEMBERSHIP SERVICES AND STUDIES

The combined manpower and membership operations, headed by Dr. Lee Gurel and a very hard-working staff, completed its first full calendar year. Contact with the district branches and with members has improved, including

updating of district branch and Central Office records; there has been increased use by the district branches of the two-card system for enrolling Members-in-Training and advancement of Members-in-Training to General Members.

We anticipate the publication of the *Biographical Directory* in November 1977; questionnaires have been sent from the publisher to all members. Included on this questionnaire was an APA mini-census that will provide this division with important manpower information. APA will not publish its Membership Directory this year because of the appearance of the *Biographical Directory*.

The division also conducted a census of residents for the academic year 1976–1977, essential as the basis for implementing the two-card system noted above and for providing important information to the profession and government planners concerning input into the psychiatric manpower pool.

We are pleased that the membership of the Association continues to grow; we attracted 1,500 new members during 1976. The net growth (after subtracting deaths and resignations) in total membership was 1,096. The total membership as of January 1, 1977, was 23,301 compared with 22, 205 on that date in 1976.

LIAISON ACTIVITIES

We have attempted to improve our liaison functions and activities during this past year. Dr. Richard Wilbur, executive vice-president of the Council of Medical Specialty Societies, attended the meeting of the Board of Trustees in December and indicated that he believed that the CMSS will become increasingly important as APA clearly defines its role in relationship to the medical specialty societies and their individual interests. Currently, APA has 5 voting members on CMSS: Drs. Paul Fink, Carolyn B. Robinowitz, Anne Seiden, Richard Shader, and L. Douglas Lenkoski. During the CMSS meeting in March 1977, Dr. Robinowitz was elected to the CMSS Executive Committee. Dr. Anne Seiden is the official CMSS representative to the Liaison Committee on Graduate Medical Education, and Dr. Richard Shader has been appointed as one of two CMSS representatives to the American Board of Medical Specialties. It is our hope that there will be a tangible and significant return on our investment in CMSS as new activities begin to show progress.

Dr. Nancy Roeske began 1977 as the APA representative to the AMA Interspecialty Advisory Board and is interested in developing a clear way for APA policies to be included in AMA deliberations. A group of APA members who serve on AMA components will meet during the annual meeting to exchange information.

Dr. John Adams serves as alternate APA representative to the AMA Interspecialty Advisory Board and as chairperson of the AMA Section Council on Psychiatry. The Section Council has increased its activities, and during the Assembly meeting Dr. Rogers J. Smith, Section Council member and delegate to the AMA House of Delegates, will report on increased APA activities there. Dr. Smith has also worked closely with the Assembly in studying the AMA Reference Committee structure.

As a member organization of the Accreditation Council for Psychiatric Facilities, APA has taken a more active role in dealing with the problems that have developed within this council because of increased activities, paucity of surveyors, etc. Our representatives to AC/PF, Drs. Francis de Marneffe, George Tarjan, and Stewart Ginsberg, have communicated closely with staff in an attempt to represent more effectively this Association's views to the Joint Commission on Accreditation of Hospitals and to the AC/PF.

The Board of Trustees wishes to further systematize these Association activities as they relate to other organizations in an effort to provide input of APA policy and to improve communications among the various representatives of this Association who work with related medical and other organizations.

CONFERENCES

APA has taken leadership in two important conferences this year. The Conference on Role Conflicts in Psychiatry, long in the planning, was held in cooperation with the Hastings Institute on March 24–26, 1977, at the Seven Springs Conference Center, Mount Kisco, N.Y. The subject was approached under four rubrics: 1) military, prisons, and schools; 2) psychiatric institutions; 3) private practice; and 4) principles and recommendations. There were 27 participants, representing psychiatry, law, sociology, and other behavioral sciences. APA participants included Drs. Jack Weinberg, Alan A. Stone, Claudewell Thomas, Melvin Sabshin, F.C. Redlich, Robert A. Moore, Robert Michels, Judd Marmor, Robert W. Gibson, Alfred Freedman, Jerome Frank, and Mr. Robert L. Robinson. A substantive report will be prepared by the Hastings Institute staff, with Mr. Robinson as consultant.

The Conference on Discharging Professional Responsibilities Through Peer Review Mechanisms was held at APA headquarters, March 11–12, 1977, in the form of four mini-conferences. In the two morning and two afternoon 3-hour sessions there were 8 participants together with staff and faculty people. Participants in the first session comprised APA leaders in peer review development in psychiatry. This was essentially a self-evaluation session of the progress that has been made and further steps to be taken. The second session involved representatives of consumer interests including representatives of retired persons, the Mental Health Association, the Mental Health Law Project, journalism, and the like. The third session was comprised of third-party payers, including representatives of several leading insurance companies, Civil Service, Blue Cross, etc. The fourth session involved experts in quality assurance and peer review technology including the Social and Rehabilitation Service, Defense Department, Assistant Secretary for Health of DHEW, Bureau of Quality Assurance, and others. A substantive report of the conference is being prepared by Mrs. Pat Vosburgh and will be published within the next three months.

Several major conferences are being planned for the remainder of 1977. A Symposium for Science Writers will be held in the late fall, sponsored by the APA Joint Commission on Public Affairs. A preliminary proposal has been submitted at the request of the Science for Citizens program of the National Science Foundation. This symposium will be an important step in our efforts to improve the quality of science reporting on the medical advances in treating the mentally ill.

A Steering Committee To Plan a National Conference on the Expressive Arts Therapies, with Dr. Robert W. Gibson as chairperson, has begun to meet. The general goal of such a conference would be to identify, explore, and seek solutions to problems that confront the associations and practi-

tioners in the expressive arts therapies. It is hoped that such a meeting would provide a forum between the expressive arts therapists and psychiatrists who have special interests and experience in art, dance, and music therapy, and group psychotherapy and psychodrama.

The Ad Hoc Committee To Plan a Conference on the Chronic Mental Patient, chaired by Dr. John Talbott, is planning a conference during January 1978. It is anticipated that the outcome of such a conference would be a policy statement for the Association on the chronic mental patient and recommendations made to the President's Commission on Mental Health.

SCHEDULING OF MEETINGS FOR 1977

The Assembly expressed its desire to have more time between the Fall Committee Meetings and the meeting of the Assembly in order for district branches and representatives and area representatives to have a chance to digest the mass of material that evolves from the meetings of the various components. In an attempt to try a new scheduling system, we have scheduled these meetings further apart in 1977 and will continue in this pattern, presumably for the next few years. The Fall Committee Meetings were scheduled for September 14–17, with the Assembly scheduled to meet October 28–30, 1977. This year there may be some problem for those who are going on trips after the VI World Congress of Psychiatry.

AREA COUNCILS

Various members of the staff have attended area council meetings during the past year, and we are working on plans and programs to allow better coordination with the area councils. We hope that this coordinating function of the staff can continue to improve. Several area councils have requested an increase in their budgets; staff will provide additional information to the Budget Committee.

ORIENTATIONS

Several years ago, an orientation session was planned by the staff for the new officers, council chairpersons, and Trustees in an attempt to explain the functions and duties of the staff in relation to the Assembly, Board of Trustees, councils, and components. A second orientation program was implemented for the district branch presidents-elect. An orientation session for district branch executive secretaries—the first of its kind—was held at the Central Office in June 1977. These sessions have proven to be quite valuable and useful. It is expected that the orientation for the executive secretaries will be conducted every several years.

OFFICERS MEETINGS

Many topics discussed at the Officers Meetings (held every summer since 1972) have now been implemented: involvement of residents in APA (we now have a new category of Provisional Membership, in addition to Members-in-Training, which will allow even earlier membership for residents); orientation sessions for officers, Trustees, council chairpersons, district branch presidents-elect, and now executive secretaries; continuing education, a requirement for continued APA membership; better Assembly-Board relationships; increased fiscal responsibility and greater efforts to manage expenses; a national review of mental health policy as reflected in the President's Commission on Mental Health; establishment and expansion of the Office of Education; and a conference on the chronic patient and on role conflicts, etc.

CLOSING REMARKS

Much has been accomplished during this past year; much more needs to be done to help in implementing recent policy decisions. Next year I hope to report additional information about our expanded activities in government operations, public affairs, education, and member benefits.

We anticipate a lively year as we work with the President's Commission on Mental Health, coordinate and improve our liaison functions, provide staff back-up for the groups considering reorganization of the APA governing structure, host a World Congress, and keep in close touch with our members through visits to district branches and area councils, etc.

I particularly want to mention the good relationships that we have had with the officers and express my personal appreciation to Dr. Robert W. Gibson who, as President, worked closely with staff and made frequent visits to the Central Office during his presidential year. It has indeed been a pleasure to have a President who has enthusiastically supported the staff's efforts to implement policies.

I would also like to offer my special thanks to the Board of Trustees, the Assembly of District Branches, its Executive Committee, the Reference Committee, the area councils, and the officers of the district branches and the Assembly for their help and support to the staff.

MELVIN SABSHIN, M.D.

Report of the Speaker

THE LAST YEAR has been marked by increasing involvement with the national community and a more aggressive stance by the representatives of the American Psychiatric Association. Psychiatrists, as professional practitioners with many missions, have become more immersed in the world around them as well as with each other. Increasingly psychiatrists have been concerned with their own identity and the extension of knowledge within this medical-psychological-social field and its application to the problems of the psychiatrically ill and to the provision of meaningful service. A somewhat angry reaction to the diffuse, ethereal, and misty concept of mental health, the politicization of the plight of the mentally disabled and the multiply handicapped, and institutional control by the naive has grown within the profession. This feeling of professional militancy has permeated Assembly endeavor and expression. In these perilous times, it was not inappropriate that a group of our brethren, the American Academy of Psychiatry and the Law, devoted its annual meeting to the topic of "Psychiatry Under Seige." Psychiatrists have increasingly attempted to speak out on behalf of their patients and themselves; as Abraham Lincoln stated, "To sin by silence when they should protest makes cowards of men."

One does not achieve acceptance and popularity by pusillanimous acquiescence and servility. On the other hand, one does not achieve professional status in a pluralistic society in the absence of sheer power, which we do not have, without communication with others and accountability for our own acts and procedures. The medical scientist is not well suited by virtue of his professionalism to compete in the marketplace of ideas; the scientific aspect of medical practice does not achieve its veracity through the media of public relations, power politics, or judicial declarations. Unfortunately, decision-makers are overwhelmed by the cacophony of self-asserted competence and the misuse of the democratic concept by those who proclaim that all ideas are created equal.

As a very complex, inherently multidisciplinary group, psychiatrists have been forced to recognize that the family of psychiatry houses many siblings and that a commune is not necessarily a community. We cannot dissipate our energies focusing on mythologies when the realities themselves tax our capacities. In this effort to unify without regimentation, all levels of organized psychiatry have worked more closely in this last year. The hydra-headed monster of Central Administration, Board of Trustees, district branches, councils and committees, legislative network, and Assembly may yet turn out to have one head and one body.

The most significant effort in the last year has been the attempt to restructure representative authority within the Association. Members of the Assembly and of the Board have worked laboriously and lengthily to evolve a slimmer and more efficient system of governance. The Assembly in its fall meeting reviewed in extended discussion proposed constitutional changes and cautiously rejected a number of plans while continuing the process of negotiation and review. This hesitance bespeaks well of a maturity that treads delicately between impulsivity and paralysis.

The Assembly has not restricted itself to the production of gaseous vapors. A significant event has been the limited representation made available for members of certain defined minority or underrepresented groups on a trial or limited time basis. Black, Hispanic-speaking, women, American Indian, and Asian-American psychiatrists have been provided with a forum within the Assembly. The Assembly authorized its Executive Committee to structure a five-year program, recognizing that the ultimate goal is participation by all our members in and through the district branches and a truly adequate representational system for psychiatrists whose prime identity will be that of their profession.

Special Assembly task forces have dealt with two major issues of the day. One group has provided a stormy liaison with the *DSM-III* committee. Although disagreements are rampant and voices strident, the prime purpose of continuing review and input at the Assembly and Board levels has been met. An evolving issue is the sense of dissatisfaction with the community mental health center movement and an attempt to appraise its function and its accomplishment, particularly as some have sought to impose this as the solitary model of mental health delivery, a concept psychiatrists increasingly see as inadequate to its purported goals. Psychiatrists are concerned both about the increasing restrictions on private health care and the collapse of state services in many parts of the United States. While the scenario remains to be written, many are working on the script.

The Assembly has increasingly reflected the wish of organized psychiatry to march forward as a medical specialty. Perhaps the Assembly was in the forefront in this regard which is now so clearly and proudly proclaimed by our training institutes and numerous other spokesmen. The Assembly has recognized that psychiatrists will have to work with greater diligence in this medically competitive world to continue to attract the best and the brightest into our profession. We have recognized that our numerous practitioners reflect a plethora of philosophies, cultures, life-styles, races, sexes, and many other categorizations that ordinarily and unfortunately are used to divide mankind, not to unite it.

If we are to be sensitive to the demands of our governments and to the needs of our patients, then indeed we must be exquisitely attuned to those factors which promote psychiatric knowledge and practice. The work of professionalism ethically applied is a noble task. We need not be defensive about proclaiming virtue where it is merited while keeping in mind the words of the Chinese philosopher, Lao-Tse, who said, "There is no greater injury to one's character than practicing virtue with motivation." As psychiatrists we can accept the fact that appropriate motivation is not a vice and that passive acquiescence to the demands of the ill-informed is certainly no virtue.

This is an edited version of the report presented by the Speaker-Elect of the Assembly of District Branches to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

Accomplishment in medicine or organizational structure is not dramatic. Our medical revolutions in retrospect have generally been the manifestation of tediously obtained, unexciting accretions of expanding knowledge cautiously applied. Perhaps the concept of the cautious revolution can best characterize the progress of the Assembly and the American Psychiatric Association in this last year as we have inched forward through the swirling maelstrom and chaos of the seventies to what we hope is a better tomorrow.

IRWIN N. PERR, M.D., J.D.

Report of the Speaker-Elect

THE ASSEMBLY OF DISTRICT BRANCHES of the American Psychiatric Association moves at an irregular pace and in an irregular pattern. The turbulence of the 1960s precipitated attention to our own governance. We have agonized at length over becoming more democratic and involving all groups in the decision-making process. Despite the appointment of committees and commissions, achieving the objectives agreed upon at the Key Conference has proven elusive. Much, however, has been accomplished. Our President, Speaker, and Medical Director have articulated an extensive list of accomplishments during the past year. Many changes have occurred, especially the implementation of recommendations originating from the Key Conference. We have thus far not presented a proposed revision of our Constitution and By-Laws, despite our extensive efforts. A revision "by petition" is in the works and may produce the hoped-for changes and improvements. A good plan implemented now is better than an excellent plan ready next year.

During the next year I look forward to the following:

1. An orientation session for executive secretaries of district branches. District branch staff can benefit from the expertise of the Central Office staff by working closely with them.

2. A strengthening of our area council efforts and activities. The APA Central Office is studying the feasibility of assisting area councils with such items as agenda, mailing, budget planning and expenditure control, and closer liaison with Central Office activities. As area councils become more active, we must face the issue of uniform funding. Some area councils assess their members as much as $25 per year to finance council activities.

3. A revision and update of the guidelines for district branch activities. A "how-to-do-it" manual can do much to complement our executive secretaries' orientation.

4. The development of some type of reference committee; this is necessary because of the volume of Assembly business. Matters must be considered by smaller groups to prevent our becoming a discussion group or committee of the whole.

Several additional activities can be started during the next year but will probably take more than a year to complete.

1. A closer relationship between the Assembly and the councils can be initiated at the Fall Committee Meetings by scheduling meetings of the various Assembly representatives and the Speaker-Elect, who serves as a member of the Reference Committee.

2. The technical process of a membership survey was demonstrated several years ago when the members were surveyed on approximately 20 issues facing our organization. A nonbinding solicitation of member opinion via total membership response or a sample survey on 20 to 40 brief issues can be done at dues payment or election time and can alert the leadership to the opinions of the members.

3. Last year the Assembly revised the method of establishment of its district branches. Many of our district branches are too small to effectively manage the many problems that face them, and several are too large to effectively represent their many members. Paradoxically, some of our largest district branches have their officers serving in multiple roles. Each district branch needs to reassess itself in terms of the newly established procedure for district branch formation.

I have heard much over the past year about who has the power in APA. Is it the Board of Trustees or the Assembly of District Branches? It is neither. The power of the American Psychiatric Association rests with its members. Power is discretionary authority over decision making. This power is exercised through a system of representation and delegated authority, periodically renewed, i.e., the democratic process. We have a strong, viable organization; we have a large and increasing membership of talented, able, and competent members. Their leaders must make it possible for them to contribute these talents and abilities to the greatest benefit of all of us.

DANIEL A. GRABSKI, M.D.

This is an edited version of the report presented by the Speaker of the Assembly of District Branches to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

Report of the Committee of Tellers

THE COMMITTEE MET on March 9, 1977, at APA headquarters to certify the results of the 1977 election. In accordance with the timetable for elections approved by the Board of Trustees at its December 1976 meeting, ballots were mailed on February 1, 1977, to 21,386 eligible voting members. Fifty-seven undeliverable ballots were deducted from that number; the final number of eligible voting members was 21,329; 10,475 ballots were returned and included in the final vote tally (49.1% of the eligible voting membership).

The Tellers acted on questionable ballots held by staff pending the Tellers' decision on their inclusion. The Tellers also verified that all candidates for the 1977 election had certified the accuracy of their submitted biographical information and that all candidates had submitted the required statements of compliance with election guidelines, in accordance with guidelines approved by the Board at its December meeting.

The Committee of Tellers certified the following candidates as elected: Jules H. Masserman, M.D., President-Elect; Donald G. Langsley, M.D., Vice-President; H. Keith H. Brodie, M.D., Secretary; Mary Ann Bartusis, M.D., Trustee-at-Large; Abram M. Hostetter, M.D., Area III Trustee; and Robert A. Moore, M.D., Area VI Trustee. Because of the closeness of the races for Trustee-at-Large, Area III Trustee, and Area VI Trustee, the committee called for a hand count of the ballots; the results were the same.

The Committee of Tellers certified that all amendments to the Constitution and By-Laws and the amendment authorization had passed.

The Committee of Tellers' report was presented to the Board of Trustees on April 1, 1977, and the following recommendations were approved: 1) to accept the results of the 1977 election; 2) to include in the *Operations Manual* the statement that official election envelopes will contain only one ballot; and 3) to refer the issue of accepting ballots postmarked with the deadline date of receipt to the Ad Hoc Committee on Election Procedures.

The Board delayed disposing of the ballots until after the annual meeting in Toronto. Election costs to date, excluding costs of keypunching and tallying the ballots, are $9,281.

LOUIS F. RITTELMEYER, M.D.

This is an edited version of the report presented by the Committee of Tellers to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

Report of the Membership Committee

THE APA MEMBERSHIP COMMITTEE met October 27–28, 1976, to consider policy and procedural issues and to process applications for various changes in membership status. On October 29, 1976, the committee met jointly with the Assembly Membership Committee to discuss and act on policy items referred by the Board of Trustees to both the committees for joint consideration.

Because the Board of Trustees on several recent occasions has expressed concern about the process and validity of the selection of Fellows, considerable discussion was devoted to this matter.

Processing nominations for Fellowship is a difficult and sensitive task. A very narrow line must be maintained between setting standards that are unfair to the nominee because they are too strict and letting standards fall so low that attaining the status of Fellow becomes meaningless. Unfortunately, the care with which the various district branches screen their nominees is quite variable, and the information available to the Membership Committee is frequently less than complete. Although the committee attempts to be fair at all costs, it tends to be lenient when truly in doubt. District branches and members frequently criticize our failure to approve Fellowship for certain members; on the other hand, to my knowledge, we have never received thanks from those marginal members who are approved.

The committee reviewed the entire process carefully, looking for possible improvements. Among alternatives discussed were more specific definition of categories for significant contributions, differential weighting of the categories, and the addition of other categories. While it was recognized that the membership needs a better explanation of the process, major changes were rejected.

The Membership Committee continues to believe that Fellowship should be reserved for outstanding APA members whose contributions have both breadth and depth; therefore, the committee requires significant and continued contributions in at least four of the seven identified categories: certification; activities in APA, district branches, and other medical societies; non-job-related community service, civic, and social activities; clinical and administrative appointments; teaching activities; research activities; and publications. In addition, there is an "other" category in which special awards, honors, activities, etc., can be noted.

The Membership Committee continuously attempts to evaluate each member's application in the perspective of that member's geographic location and opportunities.

It has been stated that Board certification is over-emphasized under the present system. The Membership Committee continues to believe that Board certification and subspecialty degrees and certifications are important mechanisms to demonstrate a member's general competence and excellence. In addition, Board examinations can be taken by any member who would be eligible for consideration for Fellowship. A review of this year's actions showed that Board certification is helpful but not essential in attaining Fellowship

This is an edited version of the report presented by the Membership Committee to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

TABLE 1
Membership Transactions

Status	1975–1976 (12-Month Period)	1976 (9-Month Period)
New (N=1500)		
Members-in-Training		655
Associate Members		25
General Members		733
Corresponding Fellows	2	1

Transfer of General Member to Fellow	107	53
New Corresponding Member		2
Request for waiver denied, transfer of General Member to Fellow		1
Deceased (N=182)		182

status. Over 75% of nominees were Board certified, many with multiple certifications; 81% of those with and 47% without certification were approved.

The question of equal weights for all categories has also been raised. At the beginning of each session, the committee adopts a numerical system for judging all applications to establish interrater reliability within the categories. Different committee members then review different sets of nominees. Those members obviously deserving Fellowship or obviously failing to do so are then easily identified. All near-fails or near-passes are then more carefully reviewed by the entire committee until a consensus can be reached. During this process the individual's total contributions are considered. When contributions are exceptional but activities are narrow (e.g., certain researchers), or if publications are a direct result of research activities already given adequate consideration rather than other types of scholarly professional writing, the necessary adjustments are made. More "credit" is given for community activities that are not requirements for maintaining a practice or appointment on a hospital staff, since these latter activities are recognized under different categories.

In summary, the Membership Committee attempts to use good judgment, tact, and sensitivity in reviewing its APA peers. We feel a more mechanistic system would be detrimental to the exercise of these qualities of review. We recommend that the committee continue to have a balanced representation of minorities, both sexes, different types of practice, and various levels of academic interest.

Finally, it must be noted that Fellowship is a national APA honor with national standards. Difficult situations arise wherein a member does yeoman local work but cannot meet the standards of Fellowship. For these individuals we feel that special recognition at the district branch level would be more appropriate than nomination for Fellowship.

The committee recommends more care on the part of the district branches in screening potential nominees, assembling the necessary information, and forwarding only those truly thought to meet Fellowship standards. We feel that, where possible, the nomination should be initiated by the district branch rather than by the member. The variability among district branches makes the establishment of policies and procedures for nomination very difficult. However, progress has been made over the past year, as reflected in the improved percentage of approvals versus submissions.

Table 1 presents a breakdown of the 3,496 membership transactions during 1976, and table 2 shows a numerical comparison of the 1976 membership and the 1977 membership.

TABLE 2
APA Membership

Classification	As of January 1, 1976 (N=22,205)	As of January 1, 1977 (N=23,301)

JOHN R. ELPERS, M.D.

Report of the Committee on Constitution and By-Laws

THIS ASSOCIATION, under the title, "Association of Medical Superintendents of American Institutions for the Insane," adopted its first constitution in 1844. This basic document has been modified many times to keep pace with the changes in organizational structure required by the growth of the society. Prior to 1950, these changes were simply accomplished by the process of voting by members in attendance at the annual meeting. Amendments adopted in 1950 changed the process to allow for a mail ballot, considerably widening membership participation in the amendment process.

The Joint Conference Committee on the Key Conference has been working on changes in the Constitution and By-Laws for the past year. However, until the process of comment by the Board, the Assembly, and the district branches, the Committee on Constitution and By-Laws will not review the proposed changes. We do expect this to be a major part of our work during the coming year.

In addition to the annual reports, there are also petitions to amend the Constitution and By-Laws, submitted by petitioners in accordance with provisions in the CBL. Because of the extreme complexity of the process, the committee would like to review the procedure for submission of petitions to amend the Constitution and By-Laws:

1. Any voting member may initiate a petition, signed by 50 or more voting members, to amend the Constitution and By-Laws. The sponsors have until 60 days before the opening of the annual meeting to file the signed petition with the Secretary. If this is done and the petition has the required number of valid signatures, the proposal is presented to the membership at the annual meeting. You now have the petitions. No action is to be taken on the proposal. In addition, the proposal must be disseminated in full text to the entire membership, and this will be done by publication in *Psychiatric News*.

2. Any nonsubstantive changes may be made in the petitions, up to the time of printing. Ballots are usually sent to the printer in early January. Nonsubstantive changes might include changes in the wording to make a meaning clearer or to spell out an intent already indicated.

3. Petitions may be withdrawn up to the time of printing. Thus, although documents to amend the Constitution and By-Laws may be presented to the membership during the annual meeting and printed in *Psychiatric News*, they need not appear on the ballot if they are withdrawn by the petitioners.

The Committee of Tellers has already reported that all of the amendments to the Constitution and By-Laws, voted on by the membership in 1977, were approved and certified by the Tellers. There were several very important changes. Article II of the Constitution outlines the Objectives and Stipulations of the Association, and the membership voted to add an advocacy clause encompassing all who may utilize mental health services: "The objectives of the Association are . . . to promote the best interests of patients and those actually or potentially making use of mental health services." In the present climate of consumerism, it appears to be important to have this clause in our Constitution, explicitly spelled out, although this has been one of the prime objectives of the profession for many years.

Article III of the Constitution establishes a new category of Provisional Member, defined further in Chapter One, Section 4, as physicians in their first year of approved psychiatric residency or in approved internships preparatory to entering approved psychiatric residency. The Assembly proposed this new category to the committee, and we are pleased that the Association has opened its doors to first-year residents and to certain interns as we attempt to provide greater involvement of all young people in APA.

Chapter Two, Section I, now provides for denial of membership in a district branch based on criteria of ethical and professional suitability. An appeal mechanism will be available to those who are so denied membership, through the Recorder of the Assembly.

One important matter that the committee did consider was Article II, Section 2, of the Constitution, which states that no substantial part of the activities of the Association shall be the carrying on of propaganda or otherwise attempting to influence legislation. The APA Executive Committee asked the committee to consider the following question: If a substantial portion of a district branch's budget is spent on legislative matters, is the district branch in violation of the APA Constitution? The committee felt that legislative matters are not necessarily propaganda, lobbying, and/or attempting to influence legislation. However, they may be if they fall outside the objectives of the Association. If a district branch spends a substantial portion of its budget on legislative matters, it is not necessarily in violation of Article II, Section 2, of the Constitution as the question depends on exactly what the legislative matters include.

WALTER H. WELLBORN, JR., M.D.

This is an edited version of the report presented by the Committee on Constitution and By-Laws to the annual business meeting in Toronto, Ont., Canada, May 3, 1977.

1976 Annual Report of the American Board of Psychiatry and Neurology, Inc.

OFFICERS AND MEMBERS OF THE BOARD

AT ITS ANNUAL MEETING on October 17, 1976, the Board elected the following officers: Dr. Thomas W. Farmer, President; Dr. Marc H. Hollender, Vice-President; Dr. Chester M. Pierce, Secretary; and Dr. Melvin D. Yahr, Treasurer.

Dr. Richard I. Shader was elected to succeed Dr. Milton Greenblatt, who had completed his second term of four years in December 1976. Dr. John R. Calverley was elected to succeed Dr. David B. Clark, who had completed his second term of four years in December 1976.

The 1977 Directors of the American Board of Psychiatry and Neurology, Inc., are as follows:

Nominated by the American Medical Association: Dr. Robert J. Joynt* (term expires December 1976), Dr. Richard M. Steinhilber (term expires December 1977), Dr. Thomas R. Johns (term expires December 1978), Dr. James N. Sussex (term expires December 1978), and Dr. S. Mouchly Small (term expires December 1979).

Nominated by the American Neurological Association: Dr. Thomas W. Farmer** (term expires December 1977), Dr. Melvin D. Yahr (term expires December 1978), Dr. Patrick F. Bray (term expires December 1979), and Dr. John R. Calverley (term expires December 1980).

Nominated by the American Psychiatric Association: Dr. Marc H. Hollender* (term expires December 1976), Dr. Chester M. Pierce** (term expires December 1978), Dr. Alfred M. Freedman (term expires December 1978), Dr. Donald G. Langsley (term expires December 1979), and Dr. Richard I. Shader (term expires December 1980).

Nominated by the American Academy of Neurology: Dr. Audrey S. Penn (term expires December 1978) and Dr. Dewey K. Ziegler (term expires December 1978).

EXAMINATIONS

Part I

At the Part I (written) examination on April 19, 1976, 1,730 psychiatrists were tested; 1,473 (85.1%) passed, 257 (14.9%) failed. A total of 461 neurologists were examined; 392 (85%) passed, 69 (15%) failed.

For the 1977 Part I examination, 1,819 psychiatrists and 391 neurologists have accepted assignment. (See table 1 for the number of candidates declared eligible and notified for Part I in 1976 and table 2 for a comparison of these figures with other years.)

This is an edited version of the report presented by the American Board of Psychiatry and Neurology, Inc., to the American Psychiatric Association, April 2, 1977.

*These Directors have been elected to a second term.

**These Directors are serving their second term of four years and are not eligible for reappointment.

Part II

Statistics on Part II examinations administered in 1976 and 1977 to date are listed in tables 3–6.

The Board's most recent Part II examination was administered February 8–9, 1977, in Seattle, Wash., to a total of 333 candidates. Statistics on this examination are not yet available.

The Part II examination schedule for the remainder of 1977 included examinations in Washington, D.C., on April 18–19; Kansas City, Mo., on June 6–7; and Philadelphia on October 17–18. The 1977 Child Psychiatry examinations were held in Chicago on March 14–15.

CHILD PSYCHIATRY

Members of the 1977 Committee on Certification in Child Psychiatry are Dr. John F. McDermott, Chairperson; Dr. Jeanne Spurlock, Vice-Chairperson; Dr. Irving Philips, Secretary; Dr. Richard S. Ward; Dr. Joseph M. Green; and Dr. Norman Bernstein.

The Committee on Certification in Child Psychiatry examined 139 candidates, a record number, at its March 14–15, 1977, examinations in Chicago compared to 106 candidates in 1976. The committee continued to offer its "retake option" in the 1977 examination and extended this option to reexaminees as well as those candidates taking the examina-

tion for the first time. This option allows candidates who feel they have performed badly in an oral section to repeat one oral section on the day of the examination. This option does not apply to the committee's written examination.

At a two-day retreat on March 28–29, 1977, in Tucson, Ariz., the following agenda items were discussed: 1) reconstruction of the grid for the committee's 1978 written examination; 2) revision of the Program for Special Training and Qualifications (PSTQ) guides; and 3) involvement of child psychiatry training directors in the certification process.

BOARD DECISIONS AND ITEMS OF INTEREST

The following major policy decisions were enacted by the Board in 1976:

1. Effective July 1, 1969, a passing grade on the Part I

examination dated any time since April 1, 1969, will be valid for seven years from the date of passing. All individuals holding such a grade may apply or reapply for the Part II examination.

2. Candidates who do not pay the Part II examination fee for their scheduled examination by the deadline specified will be removed from the roster of candidates for that examination. Such candidates will be required to submit a Part II application and the examination fee in order to be scheduled for a future Part II examination.

Candidates who pay their Part II examination fee but fail to appear at their scheduled examination will forfeit the fee. Such candidates will be required to submit a Part II application and a new examination fee in order to be scheduled for a future Part II examination.

Candidates submitting the Part II application may be required to wait one year, and possibly longer, before the Board will have sufficient examination space to schedule them.

Candidates submitting the Part II application will be billed for the Part II examination at the time they are scheduled. See appendix 1 and appendix 2 for additional policy changes.

At its June 19–20, 1976, business meeting in Minneapolis, Minn., the Board took the following significant actions:

1. Went on record in favor of greater regionalization of Part II examiners. Adopted guidelines which specify that the majority of examiners come from the region in which the examination is being conducted.

2. Decided on a new scoring system for the Part I examination. Discontinued use of the American-Canadian reference group, and substituted a standard deviation approach.

3. Agreed to substitute one videotaped examination for one live patient examination in Psychiatry and Neurology, beginning with the October 1977 Part II examination in Chicago. Under the new examination format, each Psychiatry candidate will take three hours of examination: one hour interviewing a psychiatric patient, one hour viewing a videotaped interview with a psychiatric patient and then being quizzed by an examiner, and one hour interviewing a neurological patient. The Neurology candidates will take a four-hour examination: one hour interviewing a neurological patient, one hour viewing a videotaped interview with a neurological patient and then being quizzed by an examiner, one hour interviewing a psychiatric patient, and one hour interviewing a child neurology patient.

4. Agreed to deny a proposal that ABPN join with the American Board of Physical Medicine and Rehabilitation to establish a joint certification program in EEG.

5. Agreed to explore with interested neurologists the possibility of developing a proposal, under the aegis of ABPN, regarding standards for special competence and training in electromyography (EMG) for the ABMS with requirements acceptable to ABPN.

At its November 18–20, 1976, policy meeting, the Board took the following actions:

1. Reviewed the results of a study done by Dr. Donald Langsley on the Chicago Part II examination (October 18–19, 1976). The study involved nearly 1,000 candidates and compared their performances on the live patient and audiovisual examinations. Between live patient and audiovisual Psychiatry and between live patient and audiovisual Neurology the concurrence was 84% and 86%, respectively. Dr. Langsley also presented evidence that the audiovisual examination was well accepted by Psychiatry and Neurology candidates and examiners.

2. Reaffirmed its earlier decision not to assume responsibility for certification in Administrative Psychiatry.

3. Approved the following resolution: "The ABPN recommends that only specialist site visitors be used to evaluate programs in Psychiatry and Neurology. The present system does not provide the necessary information for proper evaluation of training programs." It was agreed that the above resolution should be sent to the Residency Review Committee and promulgated to the ABMS, the Coordinating Council on Medical Education, and the Board's sponsoring societies.

4. Agreed that Dr. Marc Hollender be granted funds and authorization to invite certain psychiatrists and neurologists to develop questions for a written examination to go with the Part II audiovisual examination.

5. Agreed to revise its Part I information booklet. The new booklet includes far more detailed information on the categories for questions in Psychiatry and Neurology and sample questions from the NBME pool.

At its business meeting on February 6, 1977, in Seattle, Wash., the Board took the following actions:

1. Agreed to revise the material for Part II examiners' orientation.

2. Decided that the Credentials Committee should hold a special meeting to consider credit for the first postgraduate year abroad, the PSTQ plan, credit for psychiatry candidates with two years of training in general psychiatry and one year of training in child psychiatry, D.O. internships, and interpretation of the requirement for four months in a primary care specialty.

3. Agreed that for the 1977–1978 Part II examination cycle, beginning in October 1977, the following examinations would be authorized and added to the format currently being used: one audiovisual examination in Child Neurology for child neurology candidates, and one audiovisual examination in Neurology for psychiatrists to include, if possible, a written examination.

4. Decided to enlarge the Steering Committee on Recertification to include two representatives from each of the Board's constituent organizations—the Steering Committee for Psychiatry, chaired by Dr. S. Mouchly Small, and a Subcommittee for Neurology, cochaired by Dr. Dewey Ziegler and Dr. Jerry Chutkow. The steering committee agreed that the recertification procedure would be devised to test competence in the major specialty. Any tests for competence in the minor specialty would include only material that was relevant and necessary for the optimal clinical care of patients in the major specialty. The Steering Committee has not yet set a date for recertification but plans to do so at its next meeting.

APPENDIX 1
Policy for Retaking of Part II (Oral) Examination*

FOR PSYCHIATRY CANDIDATES

1. A candidate for certification in psychiatry who passes both Psychiatry sections of his/her Part II examination need

*This policy applies to all candidates who have passed the Part I (written) examination since June 1969 or later. Candidates who have previously failed the Part II examination and who do not now have an active Part II application on file must submit a Part II application to the Executive Office of the American Board of Psychiatry and Neurology, Inc., in order to be scheduled for a Part II examination under the new policy. The candidate's most recent pass on the Part I examination will be considered the effective date for the beginning of the seven-year period.

not repeat this part of the examination within seven years following the date of successful completion of the Part I examination. To pass the Psychiatry portion of the Part II examination, the candidate must achieve final grades of 75 or above on both Psychiatry sections of the examination.

2. A psychiatry candidate who fails one or both sections of the Psychiatry examination must take two hours of examination in Psychiatry at each subsequent examination until he/she passes both sections or until the expiration of the seven-year period following successful completion of the Part I examination.

3. Any candidate for certification in psychiatry who passes the Neurology portion of his/her Part II examination need not repeat the Neurology portion of the examination within a period of seven years following the successful completion of the Part I examination.

FOR ADULT NEUROLOGY CANDIDATES

1. A candidate for certification in adult neurology who passes both sections of his/her Adult Neurology portion of the Part II examination need not repeat this part of the examination within a period of seven years following the date of successful completion of the Part I examination. To pass the Adult Neurology portion of the Part II examination, the candidate must achieve final grades of 75 or above on both Adult Neurology sections of the examination.

2. A candidate in adult neurology who fails one or both sections of the Part II Adult Neurology examination must take two hours of Adult Neurology at all subsequent Part II examinations until he/she passes both sections or until the expiration of the seven-year period following successful completion of the Part I examination.

3. A candidate for certification in adult neurology who passes the Psychiatry portion of the Part II examination need not repeat this part of the examination within a seven-year period following successful completion of the Part I examination. The same provision applies to adult neurology candidates who pass the Child Neurology portion of the examination.

FOR NEUROLOGY WITH SPECIAL COMPETENCE IN CHILD NEUROLOGY CANDIDATES

1. A candidate in child neurology who passes both sections of his/her Child Neurology portion of the Part II examination need not repeat this part of the examination within a period of seven years following the date of successful completion of the Part I examination. To pass the Child Neurology portion of the Part II examination the candidate must achieve final grades of 75 or above on both Child Neurology sections of the examination.

2. A candidate in child neurology who fails one or both sections of the Part II Child Neurology examination must take two hours of Child Neurology at all subsequent Part II examinations until he/she passes both sections or until the expiration of the seven-year period following successful completion of the Part I examination.

3. A candidate for certification in Child Neurology who passes the Psychiatry portion of the Part II examination need not repeat this part of the examination within a seven-year period following successful completion of the Part I examination. The same provision applies to Neurology with Special Competence in Child Neurology candidates who pass the Adult Neurology portion of the examination.

APPENDIX 2
Current Regulations for Conditioning or Failing the Part II Examination*

FOR CERTIFICATION IN PSYCHIATRY

2 hours of Clinical Psychiatry (major)
1 hour of Clinical Neurology (minor)
Failure**=failing 1 hour major and 1 hour minor
Condition***=failing 1 or 2 hours major or 1 hour minor

FOR CERTIFICATION IN NEUROLOGY

2 hours Clinical Neurology (major)
1 hour Clinical Psychiatry (minor)
1 hour Child Neurology (minor)
Failure**=failing 1 hour major and 2 hours minor
Condition***=failing 1 or 2 hours major and/or 1 hour minor or 2 hours minor

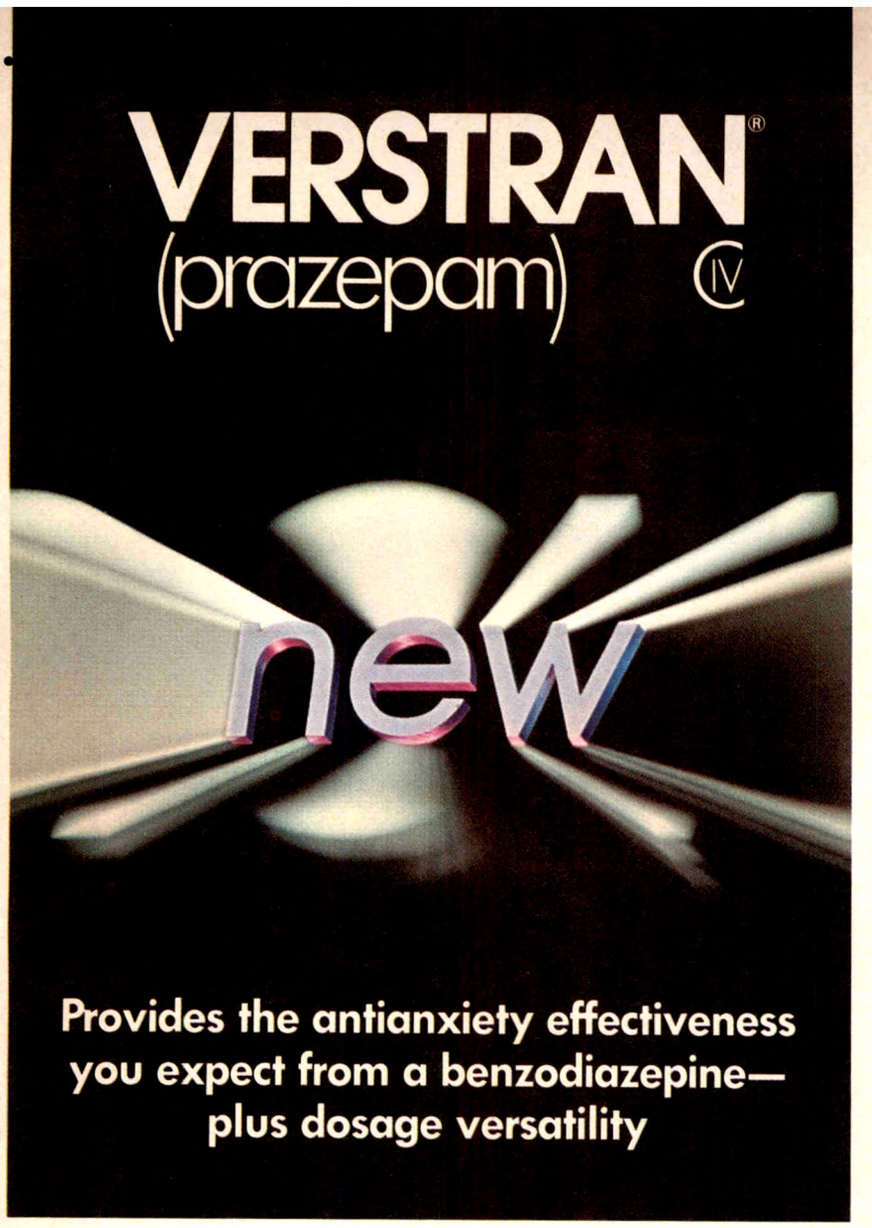
FOR CERTIFICATION IN NEUROLOGY WITH SPECIAL COMPETENCE IN CHILD NEUROLOGY

2 hours Child Neurology (major)
1 hour Clinical Psychiatry (minor)
1 hour Clinical Neurology (minor)
Failure**=failing 1 hour major and 2 hours minor
Condition***=failing 1 or 2 hours major and/or 1 hour minor or 2 hours minor

FEE SCHEDULE FOR REEXAMINATION

Failure=$190.00
Condition of major=$190.00
Condition of minor=$140.00

*A candidate must pass both hours of his/her major at the same Part II examination. If one hour of the major is conditioned, both hours of the major must be repeated.
**A candidate who fails his/her initial Part II examination must repeat and pass the entire Part II examination.
***A candidate who conditions his/her initial Part II examination must repeat and pass those subjects he/she failed originally.



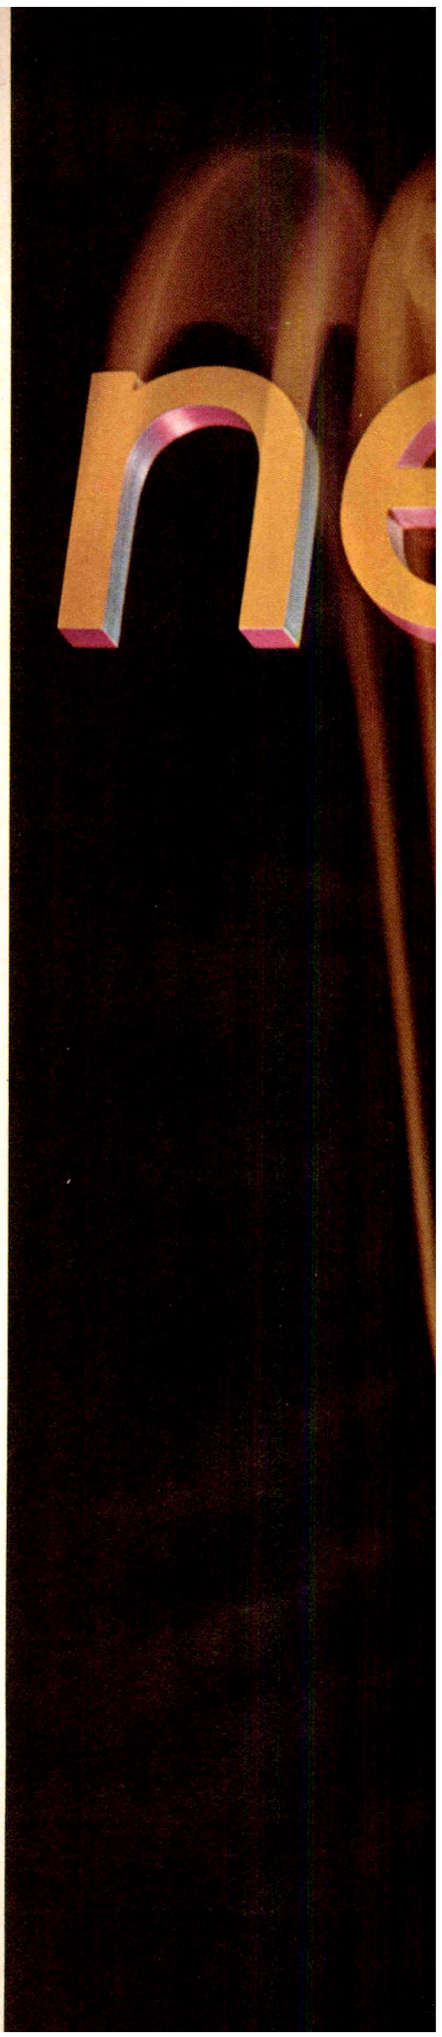
LESTER H. RUDY, M.D.
Executive Director

Warner/Chilcott Introduces

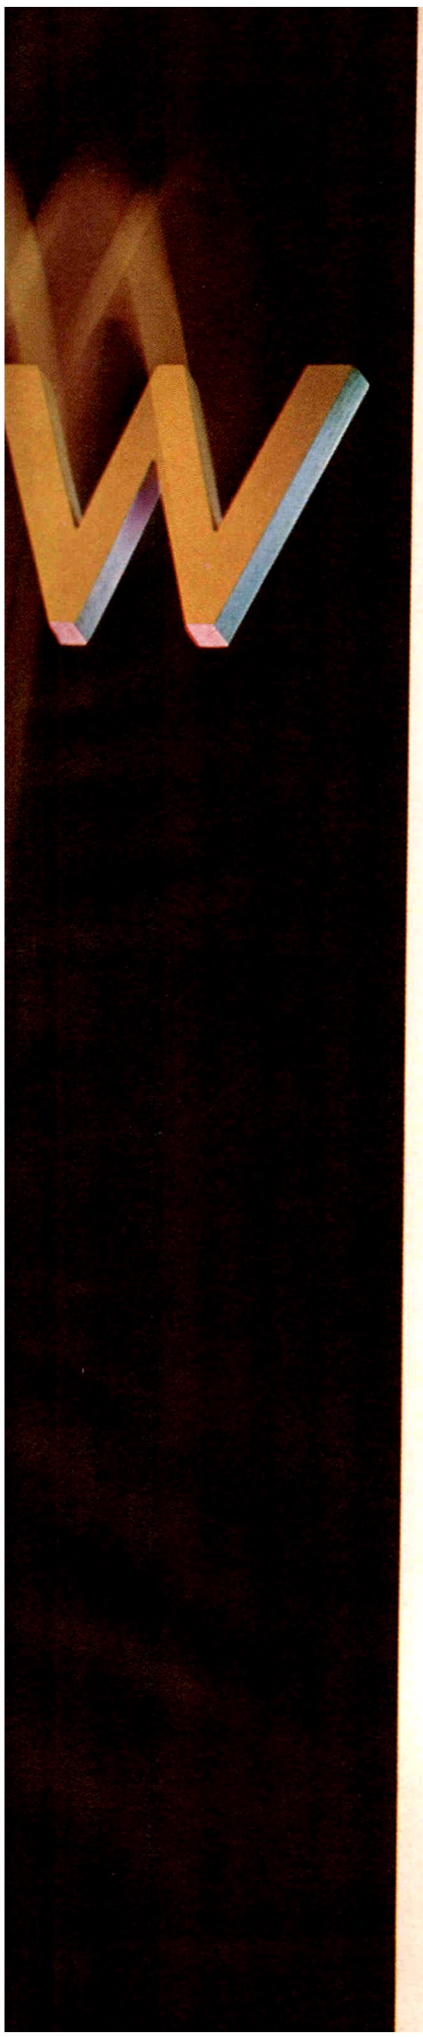
VERSTRAN®
(prazepam) C IV

A new addition for the treatment of anxiety

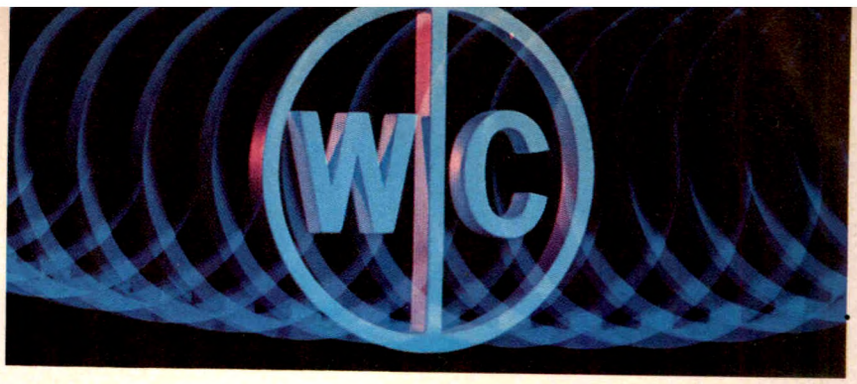
Provides the antianxiety effectiveness you expect from a benzodiazepine—plus dosage versatility



New Verstran can be administered in daily divided doses or once a day at bedtime

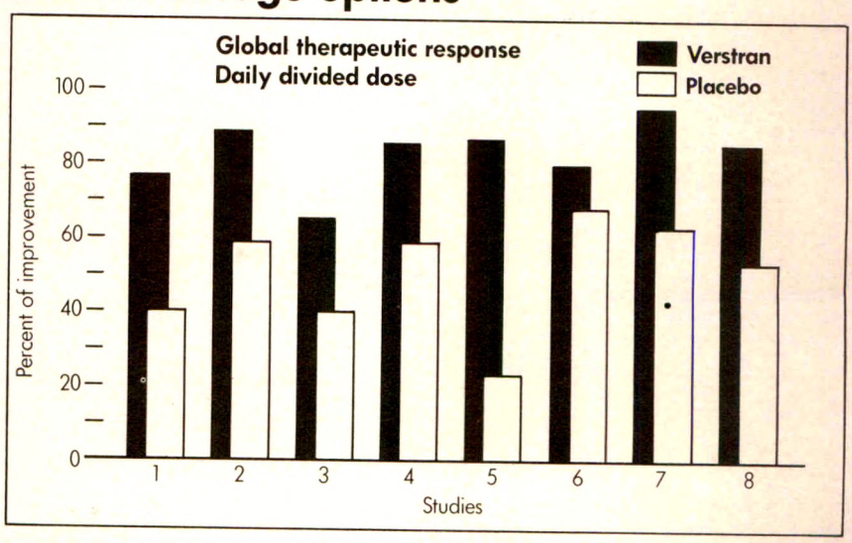


Option 1: A daily divided dose

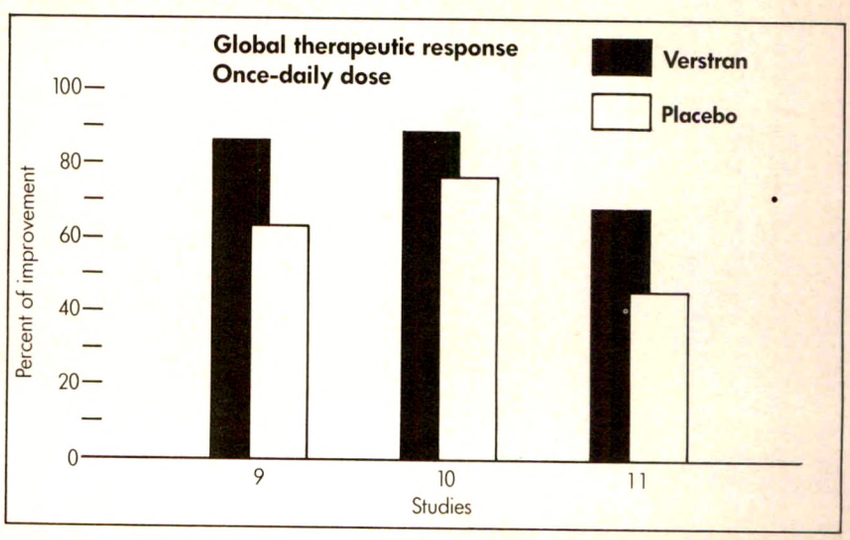


For those anxious patients who need the reassurance of multiple daily doses, the recommended starting dose is 10 mg B.I.D. This dose may be titrated gradually within a range of 20 to 60 mg per day in accordance with response.

Option 2: A once-a-day dose at bedtime



Taken in a single daily dose at bedtime, Verstran helps reduce the symptoms of anxiety—whether psychic or somatic in origin—throughout the following day. The usual starting dose for this regimen is 20 mg (two 10 mg tablets). Optimum dosage usually ranges from 20 to 40 mg daily.

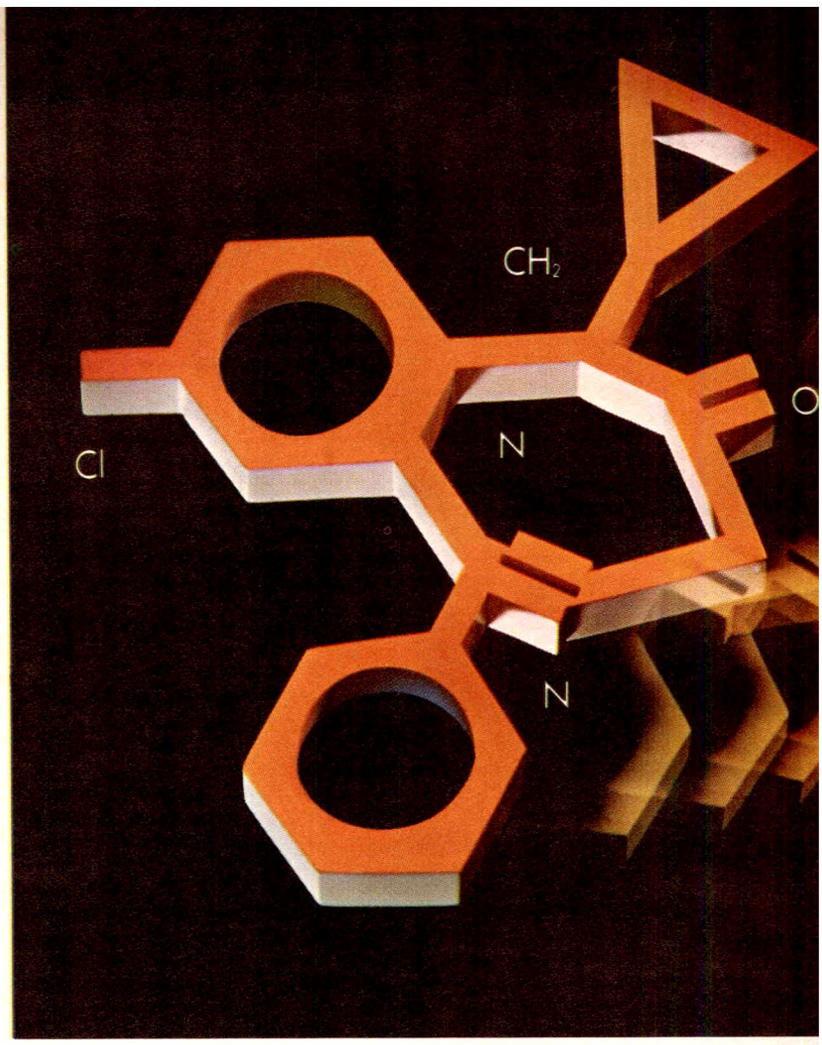


Eleven double-blind studies totaling 560 patients confirm the clinical efficacy of both dosage options*†

Four hundred and four patients suffering nonpsychotic clinical anxiety were given Verstran (228 patients) or placebo (176 patients) in a daily divided dose according to a randomized, double-blind design. Dosage of Verstran was within the recommended limits.

Target symptoms rated include: anxiety, depressive mood, irritability/hostility, tension and insomnia. Global Improvement Ratings were made at week 2, 3, or 4.

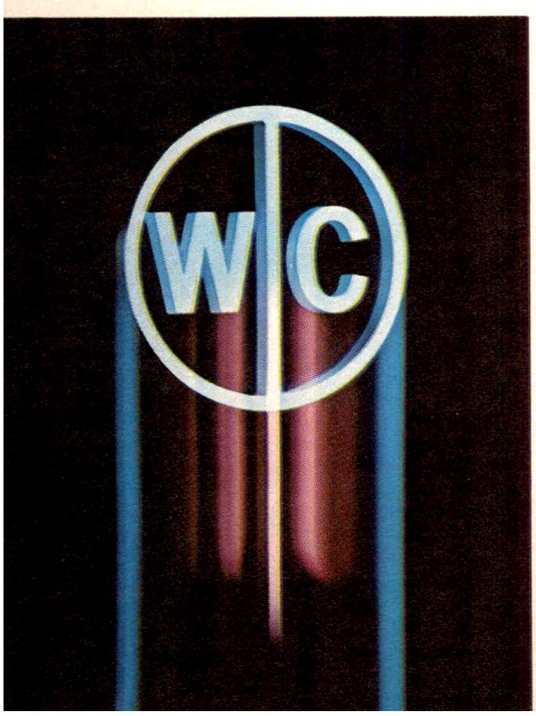
One hundred and fifty-six patients suffering nonpsychotic clinical anxiety were given Verstran (70 patients) or placebo (86 patients) once daily at bedtime according to a randomized, double-blind design. Dosage of Verstran was within the recommended limits.



Target symptoms rated include: anxiety, depressive mood, irritability/hostility, tension and insomnia. Global Improvement Ratings were made at week 3 or 4.

*Data on file, Warner/Chilcott Medical Department.

†The number of patients cited represents those evaluated at final observation.



Please see last page of this advertisement for full product information.

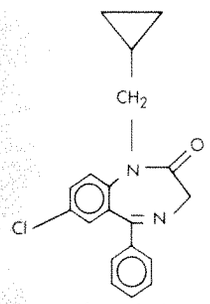
New Verstran provides the simplicity of a single 10 mg tablet strength

Verstran is available in one 10 mg tablet strength only. Titration is simplified, and dosage is easy for the patient to remember. Scored tablets facilitate precise titration.

■ **New Verstran.**
Effective for the symptomatic relief of a wide range of anxiety conditions — whether psychic or somatic in origin.

■ **New Verstran.**
The option of fully effective divided daily or single nighttime dose.

■ **New Verstran.**
The simplicity of a single tablet strengt



■ **New Verstran.**
Side effects are characteristic of benzodiazepine drugs.*

*Please see last page of this advertisement for warnings, precautions and adverse reactions.

Verstran® (prazepam) C IV

Caution: Federal law prohibits dispensing without prescription.

Description: Verstran (prazepam), a benzodiazepine derivative, is identified chemically as 7-chloro-1-(cyclopropylmethyl)-1,3-dihydro-5-phenyl-2H-1,4-benzodiazepin-2-one. The molecular weight is 324.8 and the structural formula is as follows:

Clinical Pharmacology: Studies in normal subjects have shown that Verstran (prazepam) has depressant effects on the central nervous system. Oral administration of single doses as high as 60 mg and divided doses up to 100 mg t.i.d. (300 mg total daily dose) were without toxic effects.

Single oral doses of Verstran in normal subjects produced peak blood levels at 6 hours postadministration, with significant amounts still present after 48 hours. Verstran was slowly absorbed over a prolonged period, rather constant blood levels were maintained, and excretion was prolonged. The mean half-life of prazepam measured in subjects given 10 mg t.i.d. for one week was 63 (± 15 s.d.) hours before and 70 (± 10 s.d.) hours after multiple dosing—a nonsignificant difference. Human metabolism studies showed that prior to elimination from the body, prazepam is metabolized in large part to 3-hydroxyprazepam and oxazepam.

Indications: Verstran (prazepam) is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

Contraindications: Verstran (prazepam) is contraindicated in patients with a known sensitivity to the drug and in those with acute narrow angle glaucoma.

Warnings: Verstran (prazepam) is not recommended in psychotic states and in those psychiatric disorders in which anxiety is not a prominent feature.

Patients taking Verstran should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery, including motor vehicles.

Because Verstran has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, including phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. The effects of alcohol may also be increased.

Physical and Psychological Dependence: Withdrawal symptoms similar in character to those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepine drugs. These symptoms include convulsions, tremor, abdominal and muscle cramps, vomiting and sweating. Addiction-prone individuals, such as drug addicts and alcoholics, should be under careful surveillance when receiving benzodiazepines because of the predisposition of such patients to habituation and dependence.

Precautions:

Use in Pregnancy and Lactation:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. Verstran (prazepam) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug. In view of their molecular size, Verstran and its metabolites are probably excreted in human milk. Therefore, this drug should not be given to nursing mothers.

In those patients in whom a degree of depression accompanies the anxiety, suicidal tendencies may be present, and protective measures may be required. The least amount of drug that is feasible should be available to the patient at any one time.

Patients taking Verstran for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed. Hepatomegaly and cholestasis were observed in chronic toxicity studies in rats and dogs.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

Pediatric Use: Safety and effectiveness in patients below the age of 18 have not been established.

Adverse Reactions: The side effects most frequently reported during double-blind placebo-controlled trials employing a typical 30 mg divided total daily dose and the percent incidence in the Verstran (prazepam) group were: fatigue (11.6%), dizziness (8.7%), weakness (7.7%), drowsiness (6.8%), lightheadedness (6.8%), and ataxia (5.0%). Less frequently reported were: headache, confusion, tremor, vivid dreams, slurred speech, palpitation, stimulation, dry mouth, diaphoresis, and various gastrointestinal complaints. Other side effects included: pruritus, transient skin rashes, swelling of feet, joint pains, various genitourinary complaints, blurred vision, and syncope. Single nightly dose, controlled trials of variable dosages showed a dose-related incidence of these same side effects. Transient and reversible aberrations of liver function tests have been reported, as have been slight decreases in blood pressure and increases in body weight.

These findings are characteristic of benzodiazepine drugs.

Overdosage: As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

If vomiting has not occurred spontaneously, it should be induced. Immediate gastric lavage is also recommended. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though unlikely, may be controlled with Levophed® (levarterenol bitartrate) or Aramine® (metaraminol bitartrate). Caffeine and Sodium Benzoate Injection, USP, may be used to counteract central nervous system depressant effects.

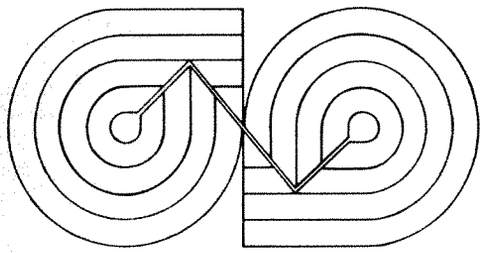
Dosage and Administration: Verstran (prazepam) is administered orally in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 20 to 60 mg daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a divided daily dose of 10 mg to 15 mg. (See Precautions.)

Prazepam may also be administered as a single dose daily at bedtime. The recommended starting nightly dose is 20 mg. The response of the patient to several days' treatment will permit the physician to adjust the dose upward or, occasionally, downward to maximize antianxiety effect with a minimum of daytime drowsiness. The optimum dosage will usually range from 20 to 40 mg.

Drug Interactions: If Verstran (prazepam) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monamine oxidase inhibitors or other antidepressants.

If Verstran is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

How Supplied: Verstran (prazepam) 10 mg light blue, scored tablets in bottles of 100 (N 0047-0276-51).



STORE BETWEEN 59°-86° F (15°-30° C).

VERSTRAN®
(prazepam) C IV

A new addition for the treatment of anxiety – whether psychic or somatic in origin

PKSAP-III

PSYCHIATRIC KNOWLEDGE AND SKILLS SELF-ASSESSMENT PROGRAM

CONTINUOUS OFFERING

PKSAP-III is again available. The Program, initially available to physicians in Spring/Summer, 1977, will differ in that central scoring services will not be provided. Each registrant will receive the question booklets, the Reference guidebook containing the correct answers and bibliography, a score worksheet, and the Performance Data Report, which will facilitate self-scoring, follow-up reading and study at the participant's convenience. For further program details, the Bulletin of Information, is available upon request to the APA, Office of Education.

To register, remit the appropriate fee with this application form to the APA, PUBLICATIONS SALES. PLEASE MAKE CHECKS PAYABLE TO APA, PKSAP-III.

INTRODUCING
NEW
SINEQUAN® 75 mg
(DOXEPIN HCl) CAPSULE

©1977, Pfizer Inc.

CLEARING OF DEPRESSION
ANTIDEPRESSANT EFFECTIVENESS...
with convenient once-a-day h.s. dosage*
SINEQUAN®
(DOXEPIN HCl)
NEW 75-mg CAPSULE
Also available:
100-mg, 50-mg, 25-mg, 10-mg CAPSULES and
ORAL CONCENTRATE 10 mg/ml, in 120-ml (4-oz) bottles
*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.
See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions.

IN THE TREATMENT OF CLINICAL DEPRESSION—

NEW SINEQUAN® 75 mg (DOXEPIN HCl) CAPSULE

EXTENDS THE RANGE OF DOSAGE STRENGTHS

PROVIDING ANTIDEPRESSANT EFFECTIVENESS

IN ADDITION TO OTHER, OFTEN BENEFICIAL, PROPERTIES...

CONVENIENT ONCE-A-DAY *h.s.* DOSAGE

which may improve patient compliance. The tota daily dosage, up to 150 mg per day, may be giver on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and the early-morning awakening often associated with depression.

ESTABLISHED ANTIANXIETY ACTIVITY

to help alleviate the anxiety which often accompanies clinical depression.

USUALLY GOOD TOLERATION

At doses up to 150 mg per day, Sinequan does no generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have occasionally been reported. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug. Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects. Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, starting dose of 25 mg t.i.d. is recommended. Dosage may subsequently be increased c decreased at appropriate intervals and according to individual response. The usual optimu dose range is 75 mg/day to 150 mg/day.

In more severely ill patients an initial dose of 50 mg t.i.d. may be required with subsequer gradual increase to 300 mg/day if necessary. Additional therapeutic effect is rarely to b obtained by exceeding a dose of 300 mg/day.

In patients with very mild symptomatology or emotional symptoms accompanying organ disease, lower doses may suffice. Some of these patients have been controlled on doses as lo as 25-50 mg/day.

As an alternative regimen, the total daily dosage, up to 150 mg, may be given on a once-a-da schedule without loss of effectiveness. This dose may be given at bedtime.

Anti-anxiety effect is apparent before the antidepressant effect. Optimal antidepressant effe may not be evident for two to three weeks.

Overdosage.

A. Signs and Symptoms

1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.

2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias an tachycardias.

Also: urinary retention (bladder atony), decreased gastrointestinal motility (paralytic ileus hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.

B. Management and Treatment

1. Mild: Observation and supportive therapy is all that is usually necessary.

2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressiv supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions t prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbe The use of activated charcoal has been recommended, as has been continuous gastric lavag with saline for 24 hours or more. An adequate airway should be established in comatose patient and assisted ventilation used if necessary. EKG monitoring may be required for several day since relapse after apparent recovery has been reported. Arrhythmias should be treated with th appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CN symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intr venous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine rapidly metabolized, the dosage should be repeated as required. Convulsions may respond t standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depre sion. Dialysis and forced diuresis generally are not of value in the management of overdosag due to high tissue and protein binding of SINEQUAN.

Supply. Available as capsules containing doxepin HCl equivalent to 10 mg, 25 mg, 50 m 75 mg, and 100 mg doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's SINEQUAN 25 mg and 50 mg are also available in bottles of 5000. SINEQUAN Oral Concentrat (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrated at 5 m 10 mg, 15 mg, 20 mg, and 25 mg. Just prior to administration, SINEQUAN Oral Concentrat should be diluted with approximately 120 ml of water, whole or skimmed milk, or orang grapefruit, tomato, prune or pineapple juice. SINEQUAN Oral Concentrate is not physical compatible with a number of carbonated beverages. For those patients requiring antidepressar therapy who are on methadone maintenance, SINEQUAN Oral Concentrate and methadon syrup can be mixed together with Gatorade®, lemonade, orange juice, sugar water, Tang®, c water; but not with grape juice. Preparation and storage of bulk dilutions is not recommende

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

HERE'S HOW WELL IT WORKS

Rapidly effective in acute schizophrenia[1]

Average length of hospitalization was 6.1 days (range 1 to 8) for 13 acutely psychotic schizophrenic patients treated with Prolixin Decanoate using the rapid neuroleptization technique. Dosage the first 72 hours averaged 73.2 mg.

Psychotic symptoms diminished rapidly during the first week and continued to abate throughout the 2-month study.

Statistically significant improvement in 13 target symptoms of the Brief Psychiatric Rating Scale, including disorientation, hostility and uncooperativeness, occurred between pretreatment and final evaluation.

Often works where others fail...[2]

Of 52 chronic schizophrenic patients, hospitalized an average 17.5 years, 71% showed clinical improvement after Prolixin Decanoate therapy (25 mg every 7 to 14 days). 32 patients were refractory to prior therapy, including haloperidol combined with chlorpromazine or thioridazine.

General mobilization of the patients was the most significant effect. 7 patients could be discharged from the hospital. In 30 patients refractory to other medication, Prolixin Decanoate tended to inhibit withdrawal symptoms.

...at a fraction of the cost

Prolixin Decanoate therapy at a maintenance dose of 25 mg. every 28 days can cost from 51% to 69% less than the lowest maintenance dosages of several oral medications (see table below).

Comparison of estimated annual hospital costs for oral and injectable therapy, given the following examples:

Drug	Assumed adult dosage*	Form and potency	Cost per unit	Annual cost
Prolixin® Decanoate	12.5-100 mg every 28 days	5 ml vials 25 mg/ml	8.5¢† per mg	$ 13.81 – 110.50
Thorazine®(SKF brand of chlorpromazine)	300-600 mg per day	100 mg tablets bottles of 1000	5.1¢ per tab.**	55.84 – 111.69
Mellaril®(Sandoz brand of thioridazine)	200-800 mg per day	100 mg tablets bottles of 1000	12¢ per tab.**	87.60 – 350.40
Haldol®(McNeil brand of haloperidol)	5-50 mg per day	5 mg tablets bottles of 1000	17.1¢ per tab.**	62.42 – 624.15
Navane®(Roerig brand of thiothixene)	20-60 mg per day	20 mg tablets bottles of 500	24.7¢ per tab.**	90.16 – 270.47

*Dosage level and interval should be determined on an individual basis, in accordance with patient's response to the particular drug as well as the manufacturer's specific recommendations for the use of the product. **Based on prices listed in 1977 Red Book.†Based on Squibb list price of $10.65 per 5 ml vial.

PROLIXIN® DECANOATE
Fluphenazine Decanoate Injection

See following page for brief summary.

PROLIXIN DECANOATE®

Fluphenazine Decanoate Injection

Often works where others fail... at a fraction of the cost

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per ml. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia or liver damage, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety and efficacy in children have not been established because of inadequate experience in use in children.

Usage in Pregnancy: Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administering this drug to pregnant patients.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with a history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams; reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 ml. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 ml. vials.

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

Order Form: Paperback Edition

Basic tool of primitive psychiatry

Fertility protective statues: For pregnant women, the statues insured a healthy, beautiful child, and protected both mother and child from the "evil eye." For sterile women, the statues' magical power aided fertility. Ashanti, Ghana.

From the collection of the Segy Gallery, New York City. Reproduced with permission.

Basic tool of modern psychiatry

Thorazine®

brand of **chlorpromazine**

Tablets: 25 and 50 mg of the HCl

- Effective control of psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings:

Caution is recommended when 'Thorazine' is administered for the treatment of vomiting in children.

Antiemetics are not recommended to treat uncomplicated short-term vomiting in children or vomiting of unknown etiology.

The possibility of extrapyramidal reactions from 'Thorazine' may confuse the diagnosis of Reye's syndrome or other encephalopathy. Although unconfirmed, some suspicion exists that centrally-acting antiemetics may contribute to or adversely affect the course of Reye's syndrome, and should be avoided in suspected cases.

©1967, 1968, 1969 SmithKline Corporation

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg. Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

Helps Return Patients to Reality

in clinically significant depression...

penetrating the symptom barrier to productive psychotherapy

symptoms often interfere with therapy

In clinically significant depression, the patient often becomes barricaded behind his own symptoms during psychotherapy. Because these symptoms can be so sharply defined and somatic in expression, he may reject the fact that they are psychic in origin. Sleep disturbance, gastrointestinal complaints, anorexia, chronic fatigue, and other psychosomatic symptoms may so preoccupy—or overwhelm—the depressed patient that truly productive therapeutic sessions are difficult to achieve. Instead of being able to concentrate on the core emotional problems of the depression itself, he may for example go on at length about how broken his sleep is or keep reiterating (while the therapeutic hour slips by) how physically miserable he feels.

ELAVIL®
(AMITRIPTYLINE HCl, MSD)
to help penetrate the symptom barrier in depression requiring medication

ELAVIL, a highly effective tricyclic antidepressant, will often alleviate these symptoms. With the help of ELAVIL, sleep disturbance—so common in clinically depressed patients and often the symptom that distresses them most—as

well as other "barrier symptoms" may be lessened to the point where they no longer come between you and the patient.

psychotherapy takes direction

As these preoccupying complaints are lifted, psychotherapy sessions can become more productive. Patients are enabled to respond more fruitfully during therapeutic hours and to resume or pursue more efficiently the necessary activities in their personal lives.

meeting therapeutic goals

And as the antidepressant activity of ELAVIL (Amitriptyline HCl, MSD) takes hold, it helps relieve the depressive condition itself. Sometimes only a minimum of actual psychotherapy is required. The patient may experience a more rapid recovery—while you conserve valuable time.

Prescribe ELAVIL then, to help lighten the patient's burden in depression—and yours in its management.

ELAVIL should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Hospitalize as soon as possible any patient suspected of having taken an overdose.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, and 150 mg
INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

an antidepressant with an anxiety-reducing sedative component to its action

MERCK SHARP & DOHME

addendum

To further simplify once-daily therapy for many depressed patients

Tablets

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

ONE TABLET, ONCE DAILY

—an appropriate way to prescribe for many depressed adult outpatients. Because of its simplicity, this regimen helps improve patient compliance. Of course, ELAVIL may also be prescribed in divided daily doses.

ONCE-DAILY DOSAGE SCHEDULE FOR ADULT OUTPATIENTS:

A single 75-mg tablet
Usual starting dosage

A single 100-mg tablet
Maximum starting dosage

A single 50-mg tablet
Minimum starting dosage

Dosage may be increased by 25 or 50 mg as necessary until a total of 150 mg per day is reached.

A single 150-mg tablet
Maximum daily dosage

ELAVIL MAY ALSO BE PRESCRIBED IN DIVIDED DAILY DOSES

The 25-mg tablet

This strength may prove useful when therapy is initiated with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime dose.

The 10-mg tablet

This strength may prove useful for patients who require lower doses, e.g., adolescent and elderly patients. For these patients who can not tolerate higher doses, 10 mg three times a day with 20 mg at bedtime may be satisfactory.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with amitriptyline HCl. Initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or a history of urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.
When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, increased intraocular pressure, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; tablets containing 150 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 30 and 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

MERCK SHARP & DOHME

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

Presenting
Lidone™
(molindone hydrochloride)
Potent non-phenothiazine
antipsychotic agent new from Abbott

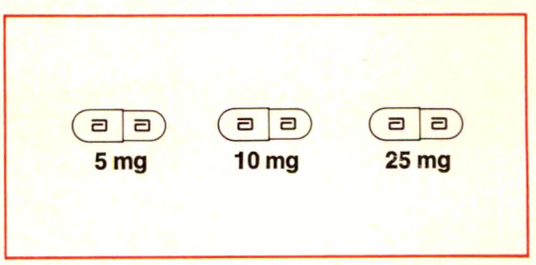
(molindone
hydrochloride)

Lidone™ treats the psychosis with little likelihood of causing excessive weight gain or problem sedation

Lidone is molindone hydrochloride, a potent antipsychotic not related to other agents. It is effective against the manifestations of schizophrenia. Yet it is largely free of certain common problems.

Normalizing weight trend seen

Unlike some potent agents, Lidone has not caused excessive weight gain. Though both weight gain and loss have been seen, the shift has typically been toward normal or ideal weight.



Benefits in alertness

Lidone is classed among the "alerting" or less-sedating group of major tranquilizers. If drowsiness does occur during initial therapy, it is usually transient. Patients on continuing Lidone therapy tend to stay alert; hence they can be more responsive to rehabilitation measures.

Improved social outlook

Patients on Lidone have shown good progress in social competence and interest. And side effects such as sexual dysfunction or weight gain, which might disrupt family or interpersonal relationships, have not been reported.

Please contact your Abbott Representative to arrange for a clinical evaluation.

Lidone™ (molindone hydrochloride)

See overleaf for prescribing information.

7083207

Brief summary of
prescribing information for

Lidone™ (molindone hydrochloride)

DESCRIPTION — LIDONE (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

LIDONE is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4(5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

ACTIONS — LIDONE (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, LIDONE antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, LIDONE exerts its effect on the ascending reticular activating system.

Human metabolic studies show LIDONE (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24 to 36 hours. There are 36 recognized metabolites with less than 2 to 3% unmetabolized LIDONE being excreted in urine and feces.

INDICATIONS — LIDONE (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS — LIDONE (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose —
20 mg/kg/day — 2 weeks, no adverse effect
40 mg/kg/day — 2 weeks, no adverse effect

Pregnant Mice oral dose —
20 mg/kg/day — 9 days, slight increase resorptions
40 mg/kg/day — 9 days, slight increase resorptions

Pregnant Rabbits oral dose —
5 mg/kg/day — 12 days, no adverse effect
10 mg/kg/day — 12 days, no adverse effect
20 mg/kg/day — 12 days, no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of LIDONE (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of LIDONE (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS — Some patients receiving LIDONE (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving LIDONE. Caution should be exercised where increased activity may be harmful.

LIDONE does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

LIDONE has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS

CNS Effects — The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological Extrapyramidal Reactions — Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia — Motor restlessness may occur early.

Parkinson Syndrome — Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome — Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System — Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological — There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with LIDONE may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects — Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with LIDONE therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with LIDONE.

Cardiovascular — Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological — Lens opacities and pigmentary retinopathy have not been reported where patients have received LIDONE (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with LIDONE.

Skin — Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with LIDONE usage alone.

LIDONE (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when LIDONE is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia — Although rarely reported with LIDONE (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to l greater in elderly patients on high-dose therap especially females. The symptoms are persiste and in some patients appear to be irreversible. Th syndrome is characterized by rhythmical involu tary movements of the tongue, face, mouth or ja (e.g., protrusion of tongue, puffing of cheek puckering of mouth, chewing movements). The may be involuntary movements of extremities.

There is no known effective treatment of tardi dyskinesia; antiparkinsonism agents usually not alleviate the symptoms of this syndrome. It suggested that all antipsychotic agents be disco tinued if these symptoms appear. Should it be ne essary to reinstitute treatment, or increase th dosage of the agent, or switch to a different an psychotic agent, the syndrome may be masked. has been reported that fine vermicular movemen of the tongue may be an early sign of the syndron and if the medication is stopped at that time th syndrome may not develop.

DOSAGE AND ADMINISTRATION — Initial ar maintenance doses of LIDONE (molindone hydr chloride) should be individualized, and th minimal effective dose should be employed. Elder and debilitated patients should be started on low dosage.

DOSAGE SCHEDULE, BASED ON SEVERITY OF SYMPTOMATOLOGY

1. Mild — 5 mg three or four times a day; an i crease to 15 mg three or four times a day may l required.
2. Moderate — 10 mg three or four times a day; a increase to 25 mg three or four times a day ma be required.
3. Severe — daily dosage as high as 225 mg may l required.

DRUG INTERACTIONS — Potentiation of dru administered concurrently with LIDONE (molin done hydrochloride) has not been reported. Add tionally, animal studies have not shown increase toxicity when LIDONE is given concurrently wit representative members of three classes of dru (i.e., barbiturates, chloral hydrate and antiparki son drugs).

MANAGEMENT OF OVERDOSAGE — Sympt matic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction absorption of LIDONE (molindone hydrochlorid which is freely soluble in water.

Since the adsorption of LIDONE (molindone h drochloride) by activated charcoal has not bee determined, the use of this antidote must be co sidered of theoretical value.

Emesis in a comatose patient is contraindicate Additionally, while the emetic effect apomorphine is blocked by LIDONE in animals, th blocking effect has not been determined humans.

A significant increase in the rate of removal unmetabolized LIDONE from the body by force diuresis, peritoneal or renal dialysis would not expected. (Only 2% of a single ingested dose LIDONE is excreted unmetabolized in the urine However, poor response of the patient may justi use of these procedures.

While the use of laxatives or enemas might b based on general principles, the amount of u metabolized LIDONE in feces is less than 1%. E trapyramidal symptoms have responded to the u of diphenhydramine (Benadryl*) and the sy thetic anticholinergic antiparkinson agents (i Artane*, Cogentin*, Akineton*).

HOW SUPPLIED — LIDONE (molindone h drochloride) capsules are supplied in bottles of 1 in the following dosage strengths and colors:

5 mg (NDC 0074-5542-13) blue and cream
10 mg (NDC 0074-5543-13) red and cream
25 mg (NDC 0074-5544-13) brown and cream.

TM — Trademark
*Benadryl — Trademark, Parke Davis and Co.
*Artane — Trademark, Lederle Laboratories
*Cogentin — Trademark, Merck Sharp & Dohme
*Akineton — Trademark, Knoll Pharmaceutical Co.

Director of Rehabilitation Services

Brentwood-UCLA Psychiatric Teaching Hospital is seeking Director of Rehabilitation Services, serving 400 inpatient and 2300 outpatients. Psychiatrists, Physiatrists, or other disciplines may apply. Services include Vocational testing, counseling, placement, and training programs, sheltered workshop, occupational therapy, education, recreation, and community projects. Experience in program development and management required, must qualify for UCLA faculty appointment. Involvement in teaching and research encouraged. Salary commensurate with qualifications; plus generous U.S. Government fringe benefits; licensure in any state acceptable; an opportunity for professional growth and personal enrichment in a fine seaside community with clean air and unexcelled academic, cultural and recreational resources. Write Milton Greenblatt, M.D., Chief of Staff, VA Hospital, Brentwood, Wilshire & Sawtelle Blvds. 530/11D, L.A., CA 90073 Phone 478-3711, Ext. 1641, Equal Opportunity Employer

PSYCHIATRISTS

Progressive community mental health center in central Arkansas needs two innovative and energetic community-oriented psychiatrists. Responsibilities include: working in small, short-term inpatient unit; providing pre- and aftercare services; consulting with staff and local medical community; and carrying a selected outpatient case load.
Excellent fringe benefits; salaries open. Interested parties contact Dr. Alan G. Tuft, Human Services Center, P. O. Box 1398, Russellville, Arkansas 72801.
The Human Services Center is an equal opportunity employer.

THE UNIVERSITY OF VERMONT COLLEGE OF MEDICINE

Department of Psychiatry

offers

a comprehensive, eclectic 4 year residency training program in psychiatry to medical graduates. The first year includes 4 months medicine/3 months psychiatry/2 months neurology and an elective. The second year, (available also to those who have completed the first postgraduate year elsewhere), includes an inpatient experience at the Medical Center Hospital of Vermont. During this year, the resident will begin longterm psychotherapy under intensive supervision. The third year emphasizes ambulatory experiences, including child and adolescent psychiatry. Rotations in consultation-liaison, community mental health and selective experiences complete the program.

Child psychiatry and psychosomatic fellowships are available.

For further information and application materials write: Barry Nurcombe, M.D., Director of Residency Training, UVM Department of Psychiatry, Medical Alumni Building, Burlington, Vermont 05401.

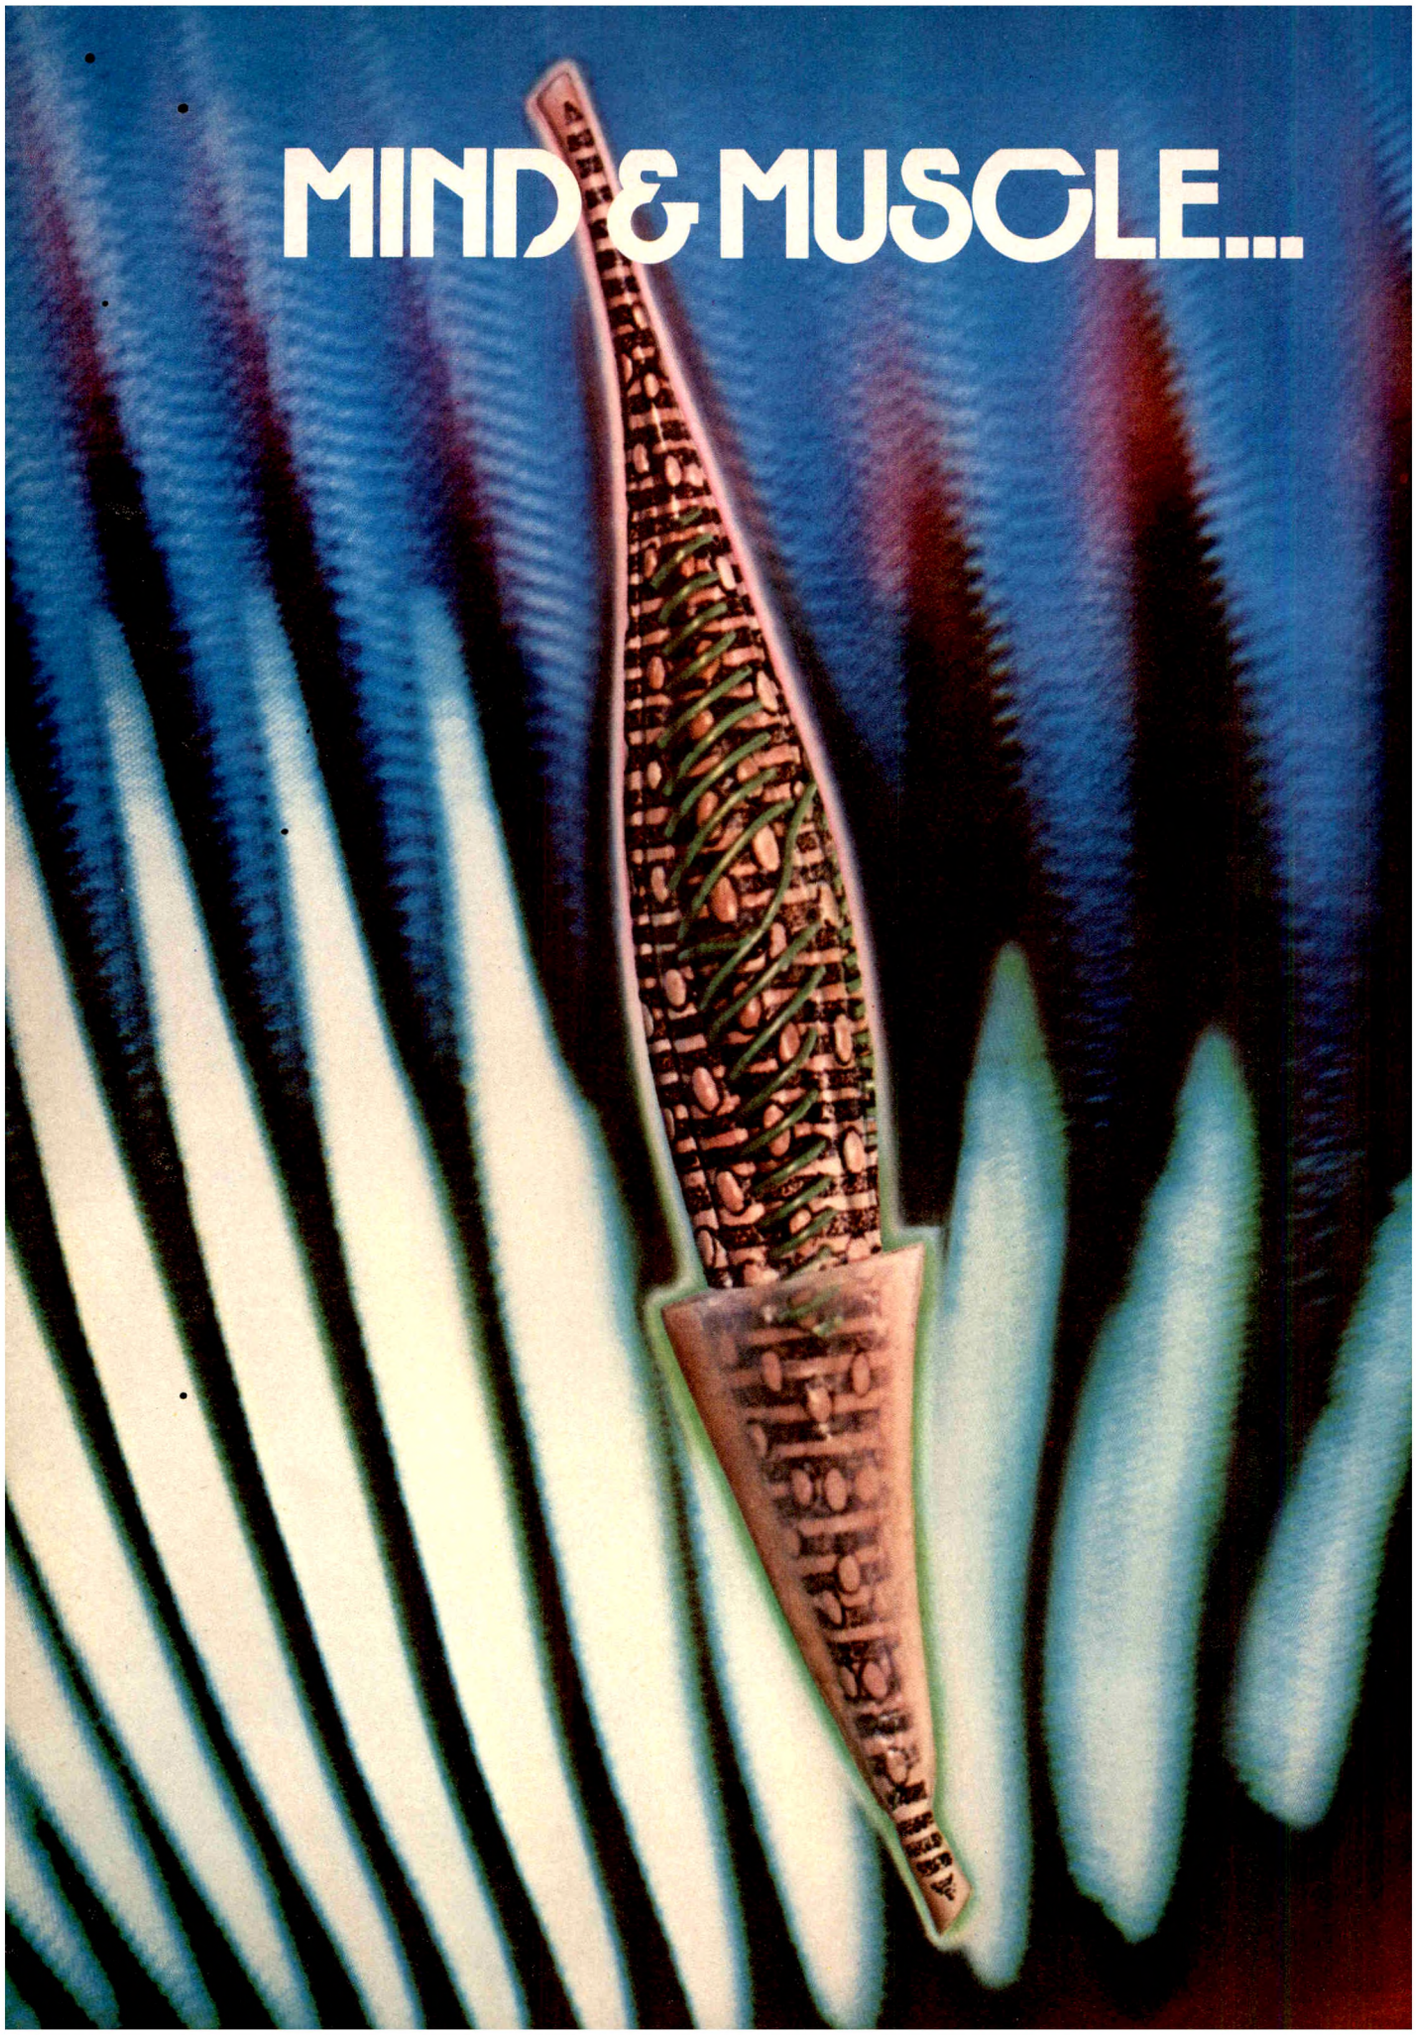
IMMEDIATE OPENINGS FOR PSYCHIATRIST AT RICHARD H. HUTCHINGS PSYCHIATRIC CENTER

THE RICHARD H. HUTCHINGS PSYCHIATRIC CENTER IS A PROGRESSIVE COMMUNITY MENTAL HEALTH CENTER LOCATED IN SYRACUSE IN CENTRAL NEW YORK. THE CENTER SERVES A FIVE COUNTY REGION AND PROVIDES PROGRAMS FOR ADOLESCENTS AND ADULTS. THE NEWLY CONSTRUCTED HOSPITAL OFFERS A WIDE VARIETY OF PATIENT SERVICES. OPPORTUNITIES INCLUDE:

RESEARCH AND TEACHING IN COMMUNITY PSYCHIATRY

A MAJOR AFFILIATION WITH SUNY COLLEGE OF MEDICINE IN SYRACUSE

INITIAL APPOINTMENT AS A TEAM PSYCHIATRIST ON A 12-24 BED MULTI-DISCIPLINARY TEAM.



OPPORTUNITIES FOR ADVANCEMENT AND ADDITIONAL RESPONSIBILITY AS THE CENTER EXPANDS.

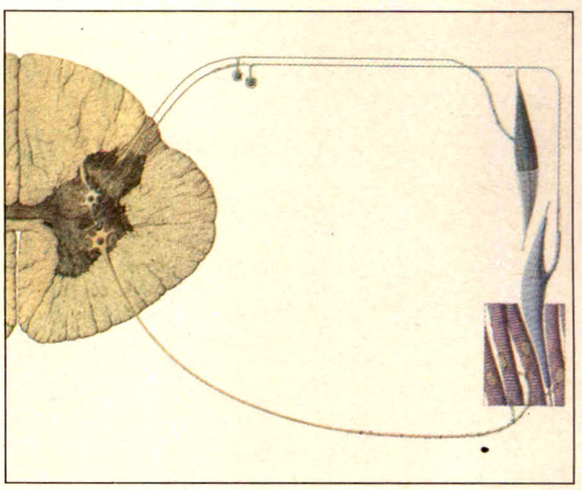
MIND & MUSCLE...



ONLY VALIUM (diazepam) HAS THESE TWO DISTINCT EFFECTS...

MIND: PSYCHOTHERAPEUTIC

alium is useful for the relief of undue sychic tension and anxiety whether seen one or associated with organic or functonal disorders, or with secondary depressive symptoms. Valium provides a quality response you know, want and trust. A esponse which has a pronounced effect n the somatic symptoms of anxiety.

MUSCLE: SKELETAL MUSCLE RELAXANT

Preliminary studies in both animals and humans have suggested that Valium (diazepam) may also work at the spinal level by enhancing presynaptic inhibition, a mechanism believed to diminish spasm in skeletal muscle. Clinically, adjunctive Valium has significant skeletal muscle relaxant properties.

VALIUM® (diazepam) IV

2-MG, 5-MG, 10-MG SCORED TABLETS

FOR THE RESPONSE YOU KNOW, WANT AND TRUST

Before prescribing, please see following page for a summary of product information.

ROCHE

A75

VALIUM®
(diazepam)

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

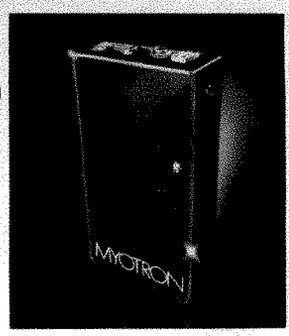
Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.



Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

Patients become easier to manage

...with a low incidence of adverse side effects on

MOBAN®
molindone HCl

- an effective antipsychotic agent
- not a phenothiazine

FAVORABLE BENEFIT/RISK PROFILE, WHICH MAY ENHANCE COMPLIANCE*

NO incidence	Tolerance development Hepatotoxic changes Ophthalmological changes Excessive weight gain Impotence Decreased libido Skin pigmentation Thyroid function changes Persistent tardive dyskinesia
LOW incidence	Sedation Adverse drug interactions Hypotension Hematological changes Lactation Amenorrhea Autonomic changes Skin rash Nonpersistent symptoms of tardive dyskinesia
MODERATE incidence	Extrapyramidal reactions

*This table compiled from clinical and field reports, according to the best available information

Further advantages with MOBAN®

The pharmacological effect from a single oral dose persists for 24-36 hours, permitting *h.s.* dosage, once the daily dosage level is established.

Several clinicians have reported that obese patients on MOBAN® frequently experienced a marked reduction in weight toward normal weight.

How to use MOBAN®

The usual starting dose is 50-75 mg/day. You can increase to 100 mg/day in 3-4 days. Titrate individually up or down depending on patient response. Some chronic, treatment-resistant patients may require an increase to 400 mg/day. (However, the long-term safety of 400 mg/day has not been established.) Please refer to complete prescribing information for further dosage instructions.

For complete prescribing information, please see next page.

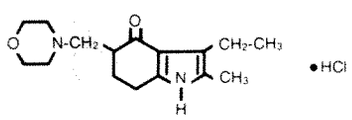
DUPONT

Patients become easier to manage on



MOBAN®

5 mg	10 mg	25 mg

molindone HCl

DESCRIPTION MOBAN® (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN® is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN® (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN® antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN® exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN® (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN® being excreted in urine and feces.

INDICATIONS MOBAN® (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN® (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in the pregnant patient have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose— 20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose— 20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose— 5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN® (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN® (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS Some patients receiving MOBAN® (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN® Caution should be exercised where increased activity may be harmful.

MOBAN® does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN® has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological

Extrapyramidal Reactions

Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia

Motor restlessness may occur early.

Parkinson Syndrome

Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome

Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System

Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological

There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN® may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects

Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with MOBAN® therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN®.

Cardiovascular

Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological

Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN® (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN®.

Skin

Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN® usage alone.

MOBAN® (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN® is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia

Although rarely reported with MOBAN® (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN® (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50-75 mg/day.

—Increase to 100 mg/day in 3 or 4 days.

—Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.

—An increase to 225 mg/day may be required in patients with severe symptomatology.

—Some chronic, treatment resistant patients, may require up to 400 mg/day (however, the long term safety of 400 mg/day has not been established).

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

Dosages may be administered once a day.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN® (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN® is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN® (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN® (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidot must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, whil the emetic effect of apomorphine is blocked by MOBAN® in animals this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN® from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN® is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based o general principles, the amount of unmetabolized MOBAN® in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles of 100 and 1000 with potencie and colors as follows: 5 mg orange, 10 mg lavender, 25 mg light green.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

Tranxene® (IV)

CAPSULES
SINGLE DOSE TABLETS

CLORAZEPATE DIPOTASSIUM 4306CB **Brief Summary**

ACTIONS—Pharmacologically, **TRANXENE** (clorazepate dipotassium) has the characteristics of the benzodiazepines. It has depressant effects on the central nervous system. The primary metabolite, nordiazepam, quickly appears in the blood stream. The serum half-life is about 2 days. The drug is metabolized in the liver and excreted primarily in the urine.

INDICATIONS—TRANXENE is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

TRANXENE is indicated for the symptomatic relief of acute alcohol withdrawal.

The effectiveness of TRANXENE for long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

CONTRAINDICATIONS—TRANXENE is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS—TRANXENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on TRANXENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since TRANXENE has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, TRANXENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. TRANXENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

TRANXENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS—In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Patients on TRANXENE for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS—The side effect most frequently reported was drowsiness. Less commonly reported (in descending order of occurrence) were: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects included insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed.

DOSAGE AND ADMINISTRATION—

For symptomatic relief of anxiety:

TRANXENE is administered orally. The capsules may be given in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 15 to 60 mg. daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a daily dose of 7.5 to 15 mg.

TRANXENE capsules may also be administered as a single dose daily at bedtime; the recommended initial dose is 15 mg. After the initial dose, the response of the patient may require adjustment of subsequent dosage. Lower doses may be indicated in the elderly patient. Drowsiness may occur at the initiation of treatment and with dosage increment.

TRANXENE-SD tablets (22.5 mg.) may be administered as a single dose every 24 hours. This tablet is intended as an alternate dosage form for the convenience of patients stabilized on a dose of 7.5 mg. capsules three times a day. TRANXENE-SD tablets should not be used to initiate therapy.

TRANXENE-SD HALF STRENGTH tablets (11.25 mg.) may be administered as a single dose every 24 hours.

For symptomatic relief of acute alcohol withdrawal:

Recommended schedule: 1st 24 hours, 30 mg TRANXENE initially, followed by 30 to 60 mg in divided doses; 2nd 24 hours, 45 to 90 mg in divided doses; 3rd 24 hours, 22.5 to 45 mg in divided doses; 4th day, 15 to 30 mg in divided doses. Thereafter gradually reduce to 7.5 to 15 mg daily, and discontinue as soon as condition is stable. Maximum daily dose is 90 mg. Avoid excessive reductions in total drug on successive days.

DRUG INTERACTIONS—If TRANXENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that TRANXENE prolongs the sleeping time after hexobarbital or after ethyl alcohol, increases the inhibitory effects of chlorpromazine, but does not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If TRANXENE (clorazepate dipotassium) is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

MANAGEMENT OF OVERDOSAGE—Overdosage is usually manifested by varying degrees of CNS depression ranging from slight sedation to coma. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

There are no specific antidotes for the benzodiazepines. The treatment of overdosage should consist of the general measures employed in the management of overdosage of any CNS depressant. Gastric evacuation either by the induction of emesis, lavage, or both, should be performed immediately. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though rarely reported, may occur with large overdoses. In such cases the use of agents such as Levophed® (levarterenol) or Aramine® (metaraminol) should be considered.

While reports indicate that individuals have survived overdoses of TRANXENE as high as 450 to 675 mg., these doses are not necessarily an accurate indication of the amount of drug absorbed, since the time interval between ingestion and the institution of treatment was not always known. Sedation in varying degrees was the most common physiological manifestation of TRANXENE overdosage. Deep coma when it occurred was usually associated with the ingestion of other drugs in addition to TRANXENE.

CLINICAL PHARMACOLOGY—Studies in healthy men have shown that TRANXENE has depressant effects on the central nervous system. Prolonged administration of single daily doses as high as 120 mg. was without toxic effects. Abrupt cessation of high doses was followed in some patients by nervousness, insomnia, irritability, diarrhea, muscle aches, or memory impairment.

Absorption–Excretion:

After oral administration of TRANXENE, there is essentially no circulating parent drug. Nordiazepam, its primary metabolite, quickly appears in the blood stream. In 2 volunteers given 15 mg. (50 μC) of ^{14}C-TRANXENE, about 80% was recovered in the urine and feces within 10 days. Excretion was primarily in the urine with about 1% excreted per day on day 10.

HOW SUPPLIED—TRANXENE (clorazepate dipotassium) is supplied as capsules in three dosage strengths:

3.75 mg. capsules (gray with white cap) in bottles of 100 (NDC 0074-3417-13) and 500 (NDC 0074-3417-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3417-11).

7.5 mg. capsules (gray with maroon cap) in bottles of 100 (NDC 0074-3418-13) and 500 (NDC 0074-3418-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3418-11).

15 mg. capsules (all gray) in bottles of 100 (NDC 0074-3419-13) and 500 (NDC 0074-3419-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3419-11).

TRANXENE-SD single dose tablets are supplied in two dosage strengths:

TRANXENE-SD 22.5 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-2997-13).

TRANXENE-SD HALF STRENGTH 11.25 mg. tablets (blue-colored) in bottles of 100 (NDC 0074-2699-13).

7043191/R

A prudent prescription for today's anxious patient

A different tranquilizer. Times change. Today's patient has changed. And the physician's most prudent choice of therapy for anxious patients may also change. Thus if you are now thinking about changing your choice of minor tranquilizers, consider Tranxene.

A change of look. Tranxene is a physically distinctive change of therapy. It's very different in form and appearance from any other tranquilizers your patients have previously received or seen.

Greater versatility. Its added dosage options are different too. They permit not only conventional divided doses, but also convenient once-a-day regimens . . . including an ultrasimple single dose tablet (11.25 mg) especially suited to elderly patients.

Yet the same effectiveness. Prescribe with confidence. In numerous published studies involving hundreds of patients, Tranxene has been shown to be clinically equivalent to diazepam in treating anxiety.

Tranxene® 4306CB C IV

Basic tool of primitive psychiatry

Fertility protective statues: For pregnant women, the statues insured a healthy, beautiful child, and protected both mother and child from the "evil eye." For sterile women, the statues' magical power aided fertility. Ashanti, Ghana. From the collection of the Segy Gallery, New York City. Reproduced with permission.

Basic tool of modern psychiatry

Thorazine®

brand of **chlorpromazine**

Tablets: 25 and 50 mg of the HCl

- Effective control of psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings:

Caution is recommended when 'Thorazine' is administered for the treatment of vomiting in children.

Antiemetics are not recommended to treat uncomplicated short-term vomiting in children or vomiting of unknown etiology.

The possibility of extrapyramidal reactions from 'Thorazine' may confuse the diagnosis of Reye's syndrome or other encephalopathy. Although unconfirmed, some suspicion exists that centrally-acting antiemetics may contribute to or adversely affect the course of Reye's syndrome, and should be avoided in suspected cases.

©1967, 1968, 1969 SmithKline Corporation

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.: Syrup, 10 mg./5 ml.: Suppositories, 25 mg. and 100 mg. Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

Helps Return Patients to Reality

GRUNE & STRATTON

IS PLEASED TO ANNOUNCE THE FORTHCOMING PUBLICATION OF

PSYCHOPOLITICS

BY MILTON GREENBLATT, M. D.

Dr. Greenblatt has had a long and productive career as scientist, teacher, clinical innovator and administrator . . .

- Professor of Psychiatry, Assistant Dean, and Director of Social and Community Psychiatry at UCLA School of Medicine
- Chief of Staff, Veterans Administration Hospital, Brentwood, Los Angeles, California
- Commissioner of Mental Health, Commonwealth of Massachusetts, 1967-1973
- President, American Board of Psychiatry and Neurology, 1976

A totally original, personal, and penetrating account of transactions between mental health and political systems by one who has lived in the psychopolitical arena for many years. An accomplished administrator, researcher, writer makes a powerful statement of the effects of socio-political forces upon the practice of psychiatry and the evolution of patient care and treatment.

Dr. Milton Greenblatt's analytical and descriptive skills are truly a match for the great problems facing mental health today. He examines issues critical for all mental health professionals, including:

- Nature of the psychopolitical system
- Political patronage and the mental health system
- Legislative regulation of psychiatric therapies
- Class action and the rights of patients
- Statewide planning for mental health
- Closing of state mental hospitals
- Establishing comprehensive community mental health centers and transitional facilities: political realities
- The search for power
- Administrator as mediator between politics and patients
- Psychiatry: the battered child of medicine

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

The American Journal of Psychiatry, formerly *The American Journal of Insanity*, is published monthly by the American Psychiatric Association. Editorial office: 1700 Eighteenth Street, N.W., Washington, D.C. 20009; telephone (202) 797-4900.

Subscriptions: U.S. $18.00 per year, Canada and South America $19.00, other foreign $22.00; single issues: $2.25 plus postage.

Business communications and changes of address from APA members should be directed to the Division of Membership Services and Studies. Communications from nonmember subscribers should be directed to the Circulation Department, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Four to six weeks' advance notice is required for changes of address.

Advertising representatives: Steven K. Herlitz, Inc., 850 Third Avenue, New York, N.Y. 10022.

Type set by Byrd PrePress, 5408 Port Royal Road, Springfield, Va. 22151.

Printed by Dartmouth Printing Co., 69 Lyme Road, Hanover, N.H. 03755.

Second class postage paid at Washington, D.C., and additional mailing offices.

Indexed in *Abstracts for Social Workers, Biological Abstracts, Chemical Abstracts, Cumulative Index to Nursing Literature, Excerpta Medica, Hospital Literature Index, Index Medicus, International Nursing Index, Nutrition Abstracts, Psychological Abstracts,* and *Social Sciences Index.*

The American Psychiatric Association does not hold itself responsible for statements made in its publications by contributors or advertisers. Unless so stated, material in the *Journal* does not reflect the endorsement, official attitude, or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

Bruce D. Snyder

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit 3 copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later. Annual meeting papers should not be submitted to the *Journal* until *after* the annual meeting.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

All communications about a manuscript should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; with other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, the copyright of all parts of the paper, including any illustrations, passes from the author to the *Journal*. Written permission to reprint material published in the *Journal* must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for this permission.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

SPECIFICATIONS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond paper. **All parts of the manuscript** (including case reports, footnotes, references, etc.) **should be double spaced,** with margins of 2½-3¾ cm (1-1½ inches) at the top, bottom, and both sides. Subheads should be inserted at reasonable intervals. All abbreviations should be explained. All measurements must be in metric units.

Length. All pages of the manuscript must be numbered, including references, tables, and figures. The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles: 3,800 words or the equivalent including references, tables, and figures (about 15 manuscript pages). Brief Communications: 2,500 words or the equivalent (about 10 manuscript pages); see stipulations above. Clinical and Research Reports: 1,000 words, 10 references, 1 table. Letters to the Editor: 500 words, 5 references. Please write the total number of words and the number of tables and figures on the title page of the submitted material.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the coauthor who has been designated to assume responsibility for the paper and reprint requests. Authors named in the by-line should be limited to principal researchers and writers; other collaborators may be acknowledged in a footnote.

Precis. A brief precis (60–100 words for regular articles, 40–60 words for Brief Communications) is included at the beginning of each article. The author may prepare the precis or ask that the *Journal* staff prepare it.

References. References should be typed **double spaced** on a separate sheet of paper. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Tables and figures should be self-explanatory and should supplement, not duplicate, text. See recent issues of the *Journal* for general style.

Each table should be typed double spaced on a separate sheet attached at the end of the manuscript. Columns of like material should read down, not across.

One complete set of figures, in the form of glossy prints, should be submitted. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Graphs should be finished drawings not requiring further artwork. Authors are urged to engage professional assistance in the preparation of figures and may be charged for any further artwork that must be done in the editorial office.

AUTHOR CORRECTIONS

After the paper has been scheduled for publication, the edited manuscript will be sent to the first-named author for corrections and answers to queries. Prompt return is necessary. If an author expects to be away from his office for a long period of time after being notified of the acceptance of his paper, he should inform the *Journal* office or arrange with a coauthor to assume responsibility for the paper. Galley proofs will not be sent to authors.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article. Requests from others to order reprints should be directed to the APA Publications Services Division; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

THE AMERICAN PSYCHIATRIC ASSOCIATION
1700 Eighteenth Street, N.W., Washington, D.C. 20009

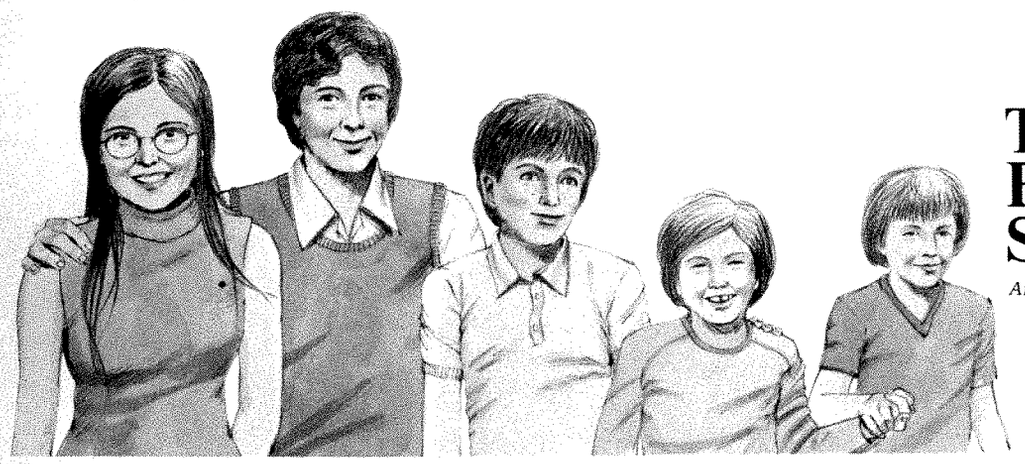
Flexibility is our forte: The Brown Schools

Because we maintain great flexibility at all three of our treatment centers, each resident follows an individualized plan of treatment, training, education and care prescribed for that resident alone.

And we believe that residential treatment conducted in this highly individualized manner still is the most effective treatment for many. Our large, experienced staff is skilled in the treatment of children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.



Our three treatment centers are geographically separated to provide the appropriate residential milieu, yet close enough that residents benefit from the comprehensive training and expertise of the entire staff. All three are psychiatrically oriented, so that we are prepared to treat emotional disturbance in persons of any intellectual capacity and of any age.

The December 1977 issue of

The American Journal of Psychiatry

will feature

- **The Brain as a Dream State Generator: An Activation-Synthesis Hypothesis of the Dream Process**

  By J. Allan Hobson and Robert W. McCarley

BOOKS IN PSYCHIATRY AND RELATED DISCIPLINES

PHENOMENOLOGY AND TREATMENT OF SCHIZOPHRENIA

Edited by **William E. Fann, M.D., Ismet Karacan, M.D., D.Sc., Alex D. Pokorny, M.D.** and **Robert L. Williams, M.D.** This wide-ranging volume covers most of the interesting and significant conceptions of schizophrenia abroad among the mental health professions today and provides a considerable amount of information concerning the tactics and details of treatment. It is an eclectic presentation which unites biological and psychodynamic approaches in an effort to understand the most disabling and disruptive of the psychiatric disorders.

1977 approx. 580pp., illus $30.00(Tent.)

PSYCHIATRY: AREAS OF PROMISE AND ADVANCEMENT

Edited by **John Paul Brady, M.D., Joe Mendels, M.D., Martin T. Orne, M.D., Ph.D.** and **Wolfram Rieger, M.D.** Beginning with a brief historical account of 200 years of American psychiatry, contributions trace advancements in, and project the future for, such areas of study as: psychobiology of schizophrenia, depression and addiction; adrenergic responses in the affective disorders; psychosurgery; psychopathology and psychopharmacology; consultation psychiatry. The book traces the trend toward establishing a scientific foundation for psychiatry through emphasis on rational scientific investigation of behavioral disorders and their psychological and biological correlates.

1977 xiv + 253pp., illus $15.00

PHENOMENOLOGY AND TREATMENT OF DEPRESSION

Edited by **William E. Fann, M.D., Ismet Karacan, M.D., D.Sc., Alex D. Pokorny, M.D.** and **Robert L. Williams, M.D.** Concerned with the etiology, diagnosis and treatment of clinical depression, this book presents biological and psychodynamic theories reflecting recent research and clinical experience. Included among the topics reviewed and analyzed are: endocrinological and biogenic amine questions; electroconvulsive therapy, novel hospital modalities; crisis intervention techniques and outpatient care; medication regimens. Diagnostic techniques are discussed by experts, as are suicide, sociological and environmental issues.

1977 xviii + 350pp., illus. $20.00

BIOLOGICAL BASES OF PSYCHIATRIC DISORDERS

Edited by **Alan Frazer, Ph.D.** and **Andrew Winokur, M.D., Ph.D.** An interdisciplinary venture into the mind and the sources of its disorders, this text explores the intricate relationship between the brain as a biological entity and human behavior. Integrating contributions from anatomy, biology, pharmacology, physiology, neuroendocrinology, genetics, psychology and psychiatry, it illustrates the fruitful partnership of basic and clinical investigations in solving practical problems and in framing fundamental questions. Based on a carefully planned biological background, it deals with substantive issues in the major behavior disorders.

1977 xiv + 271pp., illus. $15.00

DEPRESSION AND SCHIZOPHRENIA: A Contribution on their Chemical Pathologies

By **H.M. van Praag, M.D., Ph.D.** The focus is on the interrelations between disturbed cerebral function and disturbed behavior. Dr. van Praag puts forth hypotheses which, although largely derived from animal experiments, can now be clinically tested. The book summarizes and weighs the merits of work done in the last 15 years concerning the relationship between disturbed behavior and monoamines. *"If you want a lucid guided tour of the biological determinants of depression and schizophrenia, this book is it"–Contem Psychol*

1977 xiv + 260pp., illus. $20.00

AGING AND DEMENTIA

Edited by **W. Lynn Smith, Ph.D.** and **Marcel Kinsbourne, D.M.** Contents: Dementia of Old Age (Wang); Morphological Changes and Dementia in Old Age (Tomlinson); The Radiographic Morphology of Cerebral Atrophy (Pear); Vascular Disease and Dementia in the Elderly (O'Brien); Transmissible Virus Dementia: The Relation of Transmissible Spongiform Encephalopathy to Creutzfeldt-Jakob Disease (Traub, Gajdusek, Gibbs,Jr.); Intellect and Personality in the Aged (Savage); Cognition in Dementia Presinilis (Haward); Future Perspectives in Aging and Dementia (Nay); Cognitive Decline with Advancing Age: An Interpretation (Kinsbourne)

1977 xii + 244pp., illus. $15.00

PATHOGENESIS AND TREATMENT OF HEADACHE

Edited by **Otto Appenzeller, M.D., Ph.D.** All types of headache discussed from several viewpoints, including ENT, ophthalmology and neurosurgery. Both the art of treatment and the scientific basis of therapy are considered in such contributions as: An Approach to the Patient with Headache (Friedman); Psychogenic Headache and its Treatment, Including Biofeedback Techniques (Diamond); Neurosurgical Aspects of Head Pain (Walker); Migraine (Friedman); Cluster Headache (Graham); Headaches in Children (Atkinson); Disorders of Immune Mechanisms and Headache (Dalessio). An up-to-date review of current knowledge.

1976 x + 217pp., illus. $18.00

CURRENT DEVELOPMENTS IN PSYCHOPHARMACOLOGY, Volume 4

Edited by **Walter B. Essman, M.D., Ph.D.** and **Luigi Valzelli, M.D.** Contents: Opiate Receptors in the Central Nervous System (Simon); Pharmacological and Biochemical Studies with Beta-Carboline Analogs (Ho); Recent Advances in Genetics and Psychopharmacology (Mendlewicz); Psychopharmacology of Aging: Current Trends (Sathananthan, Gershon, Ferris); Catecholamines and Behavior (Engel, Carlsson); Neuropharmacology of Hyperkinesis (Silbergeld); Long Term Treatment with Neuroleptics in Psychiatry (Shepherd, Watt); Precipitated Morphine Withdrawal in Rats as a Tool in Opiate Research (Blasig, Herz); Tricyclic Antidepressants: A Review of their Toxicology (Fiori)

1977 xiv + 296pp., illus. $25.00

Hallucinations and delusions rapidly controlled

Trapped by unrealistic perceptions...

...and terrified by his hallucinations and delusions on admission. Because Navane (thiothixene) is particularly effective in controlling these symptoms and their resulting suspiciousness and anxiety, it can provide the essential first step toward restoring stabilization and facilitating the development of purposeful activity. Extensive clinical data and widespread experience confirm the effectiveness of Navane in rapidly controlling such typical psychotic behavior on admission.

Long-term therapy is facilitated...

...because Navane offers an unsurpassed safety record among effective neuroleptic agents, permitting continuing control of symptoms of psychoses such as hallucinations and delusions. Like other antipsychotic agents, extrapyramidal symptoms may occur, but are readily controlled through dosage adjustments or antiparkinsonian agents. Cardiovascular effects such as hypotension, and hepatic or hematopoietic effects rarely occur and are generally mild and transient, with no jaundice or agranulocytosis reported to date.

An effective first step towards discharge...

Navane®

(thiothixene) (thiothixene HCl)

Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. Concentrate 5 mg./ml.—Intramuscular 2 mg./ml.

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children–The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution–For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate–In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor elevating action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg. of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

NEW BOOKS

DEMENTIA

by Charles E. Wells, MD, Vice Chairman, Dept. of Psychiatry
Vanderbilt University School of Medicine

New edition—2nd / 290 pages / 40 illustrations / $22.00
Contemporary Neurology Series Vol. 15

Dementia is far too complex a subject to be covered completely by any one investigator. In this excellent 2nd edition, Dr. Wells and his 17 eminent contributors report their separate experiences in the diagnosis and treatment of dementia. Thus the book offers a scope of findings probably unmatched in any other single volume on the subject. In addition there are over 1200 references to the literature.

The first chapter is a scholarly definition of dementia—in itself well worth reading. In the following eleven chapters, over 60 possible causes of dementia are extensively reviewed from different perspectives. A variety of diagnostic examinations are detailed, including physical, mental, neurological, roentenographic, EEG and CAT scan, with a number of illuminating illustrations. Beyond that the contributors report on symptomatology, pathogenesis and, when appropriate, specific treatment therapies. This book is a timely and useful compilation of the most advanced knowledge on dementia.

CONTENTS

Dementia: definition and description
Charles E. Wells

Dementia in old age
H. Shan Nang

Diseases presenting as dementia
Gunter R. Haase

Normal pressure hydrocephalus
Robert Katzmann

Viruses and dementia
Raymond P. Roos and Richard T. Johnson

The pathology of dementia
Bernard E. Tomlinson

Biochemical approaches to dementia
James O. McNamara and Stanley H. Appel

The neurological examination in dementia
George W. Paulson

The clinical use of psychological testing in evaluation in dementia

THE MENTAL STATUS EXAMINATION IN NEUROLOGY

by Richard L. Strub, MD and F. William Black, PhD—Foreword by Norman Geschwind, MD

New book / 176 pages / 27 illustrations / $7.95 (paper)

Alone among medical texts, this new book deals exclusively and comprehensively with the mental status examination in neurology. It can help the physician determine whether emotional or behavioral change is the result of a specific organic brain disease or psychiatric impairment. It provides a basis for measuring cognitive and emotional deficits as well as residual strengths. In some cases, the information gained may relate damage to certain regions of the brain. Various tests are described in detail—giving suggested questions along with clinically useful interpretations of the probable answers. As a further practical measure, there are two helpful appendices: Standard Psychological Tests and Composite Mental Status Examination. Concise yet thorough, the book is useful for both the busy practitioner and the student.

CONTENTS

Levels of consciousness
Attention
Behavioral observations
Language
Memory
Constructional ability
Higher cognitive functions
Related cortical functions
Summary of examination
Further evaluations
Standard psychological tests
Composite mental status examination

When depression is worse in the morning...

consider the antidepressant with the a.m./h.s. option

Early morning can be the depressed patient's "darkest hour"—the time when he most feels the need for help. Taken at the low point of the classic depressive diurnal rhythm, Norpramin (desipramine hydrochloride) in the a.m. may help patients get started with daily responsibilities, and encourage participation in various forms of psychotherapy.

The a.m. option
Clinical studies show that a single daily administration of Norpramin is as effective and well tolerated as the same quantity given as a divided dosage. This means that Norpramin may be given once daily, morning or bedtime, whichever is most appropriate to the patient's therapeutic need, drug response and activity patterns. A.M. dosage of Norpramin can be especially useful when your depressed patient feels more depressed in the early morning. Morning administration may also help reduce the potential for confusion when other agents are prescribed concomitantly at bedtime.

The h.s. option
For those patients who experience a sedative response to Norpramin, a bedtime dose is most appropriate. Evening administration of Norpramin rarely produces morning hangover.

Minimal daytime drowsiness —permits an active schedule
With Norpramin, problems of daytime drowsiness and morning hangover are largely avoided. Minimal daytime drowsiness can be especially important for patients who must perform daytime activities at home or at work.

Early therapeutic response— builds hope and provides encouragement
While full therapeutic effect may require two to three weeks, onset of action has often been observed in two to five days. Although results have been variable, the weight of scientific reports suggests a faster onset of action with desipramine than with either imipramine or amitriptyline.

Norpramin®
(desipramine hydrochloride tablets NF)
25 mg., 50 mg., 75 mg., 100 mg., 150 mg.

for the patient who must function during the day

Merrell

See following page for prescribing information.

Norpramin®
(desipramine hydrochloride tablets NF)

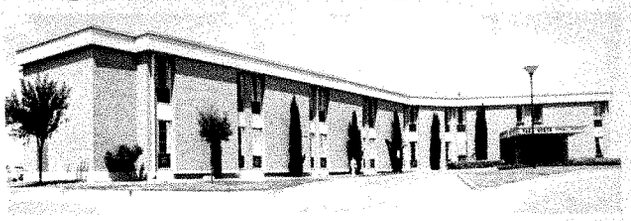
Brief Summary

Indications: Norpramin (desipramine hydrochloride tablets NF) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly. 6. In patients who may use alcohol excessively, it should be borne in mind that the potentiation may increase the danger inherent in any suicide attempt or overdosage.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. If possible, dispense in child-resistant containers. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Use cautiously with anticholinergic or sympathomimetic drugs. Response to alcoholic beverages may be exaggerated. In the concurrent administration of ECT and antidepressant drugs one should consider the possibility of increased risk relative to benefits. The sedative effects of Norpramin and benzodiazepines (e.g., chlordiazepoxide or diazepam) are additive. Both the sedative and anticholinergic effects of the major tranquilizers are additive to those of Norpramin. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is neutropenia.



Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially in the elderly), hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs. *Hematologic:* bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive); altered liver function; weight gain or loss, perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *Usual adult dose:* 100 mg. to 200 mg. per day. Dosages above 200 mg. per day are not recommended. *Initial therapy:* Should be administered at a low level and increased according to tolerance and response. It may be administered in divided doses or a single daily dose. *Maintenance:* Lower adequate dose once daily to maintain remission. *Adolescent and geriatric patient dose:* 25 mg. to 100 mg. per day, in single or divided doses. Dosages above 100 mg. are not recommended.

Five Lectures on Psycho-Analysis

The Standard Edition

By SIGMUND FREUD

Translated and edited by JAMES STRACHEY

In 1909 Freud delivered five lectures at Clark University in Worcester, Massachusetts, in what was the first official recognition of the young science of psychoanalysis. In spite of all the additions that were to be made to the structure of psychoanalysis during the following quarter-century, these lectures still provide an admirable preliminary picture and reveal the sense of form which made Freud such a remarkable expository lecturer. $6.95

Introductory Lectures on Psychoanalysis

By SIGMUND FREUD

The Standard Edition

Translated and edited by JAMES STRACHEY

The indispensable basis for an understanding of Freud and his work. The INTRODUCTORY LECTURES display Freud's gift for exposition at its height. In the first two groups, he presents his thoughts on parapraxes and the importance of dreams in a fresh and illuminating way—in the third group, he sets forth a brilliant introduction to the study and treatment of psychoneuroses. (The old translation was published under the title *A General Introduction to Psychoanalysis*.)

500 pages. $2.95, paperback. A LIVERIGHT BOOK.

The Complete Psychological Works of Sigmund Freud

The Standard Edition

Translated and edited by JAMES STRACHEY

The twenty-four volume set of the Standard Edition contains all of Freud's published psychological writings, with the primary aim of rendering Freud's meaning with the greatest possible accuracy. The translations, editorial commentaries, critical apparatus, indexes, and bibliographies make the Standard Edition an unrivalled source of reference for specialist, scholar, and student. $350.00 the set

The vulnerable ages

The first epileptic seizure is most likely to occur during early childhood and at the onset of puberty

About 9 out of 10 epileptics experience their first seizure before the age of 20—with the highest incidence between 5 and 7, when children start school, and at the onset of puberty, a time of physiological and psychic turmoil.[1] The most common type, grand mal, occurs in approximately 75% of epileptic children,[1] and more than 50% of patients who suffer initially from petit mal develop grand mal seizures before they reach the age of 16.[2]

Mysoline (primidone) for control of grand mal, psychomotor and focal epilepsy

At the onset and afterwards — used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. *Excellent* for control of grand mal. Valuable for control of psychomotor[1,3,4] and focal epilepsy as well.[5]

Add Mysoline when control with other anticonvulsants is inadequate—As concomitant therapy, MYSOLINE can improve seizure control in grand mal and psychomotor epilepsy. The combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.[6]

Change to Mysoline when other anticonvulsants fail—A changeover to MYSOLINE is frequently warranted when other anticonvulsants must be discontinued because of important side effects, or when grand mal seizures are refractory to phenobarbital, with or without diphenylhydantoin.[7]

may be the start of a better life for the epileptic

initial and maintenance therapy for
grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY
(For full prescribing information, see package circular.)

MYSOLINE® Brand of PRIMIDONE
Anticonvulsant

ACTIONS: MYSOLINE acts on the central nervous system to raise seizure threshold or alter seizure pattern. The mechanism(s) of action of anticonvulsant drugs is not known.

Primidone has anticonvulsant activity *per se*. In addition, its two metabolites possess anticonvulsant qualities. The major metabolite is phenylethylmalonamide (PEMA); the other is phenobarbital. In addition to its own anticonvulsant potential, PEMA potentiates phenobarbital.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several days before it can be assessed.

Use in pregnancy: Recent reports strongly suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Reference has been made to primidone in several cases in which it was used *in combination* with other anticonvulsants; but its teratogenicity has not been conclusively demonstrated. The possibility exists that other factors, *e.g.*, genetic factors or the epileptic condition, may contribute to the higher incidence of birth defects. The data also indicate that the great majority of mothers receiving anticonvulsant medication deliver normal infants.

Anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and risk to both mother and the unborn child.

When the nature, frequency, and severity of the seizures do not pose a clear threat to the patient, good medical practice requires that the physician weigh the expected therapeutic benefit of anticonvulsant therapy against possible risk on an individual basis.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

The physician should weigh all of the foregoing considerations when treating and counseling epileptic women of childbearing potential.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

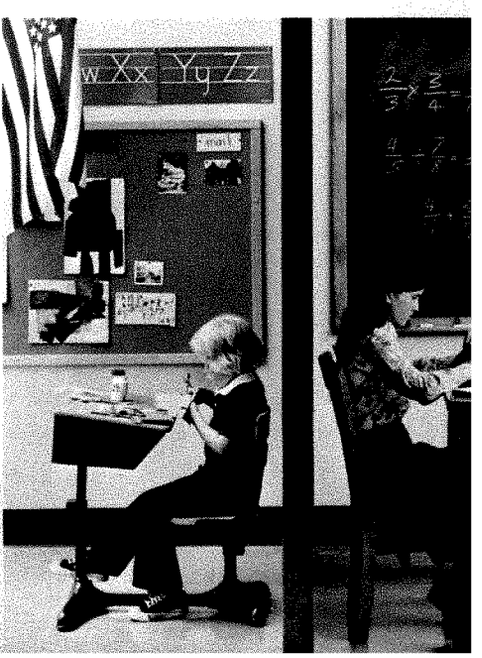
ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuir medication.

DOSAGE AND ADMINISTRATION: The avera adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 n Increments of 250 mg. are added, usually at weekly interva to tolerance, or therapeutic effectiveness, up to daily doses n exceeding 2.0 Gm. A typical dosage schedule for the introdu tion of MYSOLINE (primidone) is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age maintenance levels are e tablished by a similar schedule, but at one-half the adult dosa It is best to begin with 125 mg., with gradual weekly increas of 125 mg. a day, to a daily total usually between 500 mg. ar 750 mg.



In patients already receiving other anticonvulsant MYSOLINE should be gradually increased as dosage of tl other drug(s) is maintained or gradually decreased. This re men should be continued until satisfactory dosage level achieved for combination, or the other medication is complete withdrawn. When therapy with this product alone the objective, the transition should not be completed in le than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advanta when small fractional adjustments (upward or downwar may be required, as in the following circumstances:

- for initiation of combination therapy
- during "transfer" therapy
- for added protection in periods of stress or stressful sitt tions that are likely to precipitate seizures (menstruatio allergic episodes, holidays, etc.)

HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Eac tablet contains 250 mg. of primidone (scored), in bottles 100 and 1,000. Also in unit dose package of 100. No. 431—Eac tablet contains 50 mg. of primidone (scored), in bottles of 10 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (t spoonful) contains 250 mg. of primidone, in bottles of 8 flui ounces.

The Psychoanalytic Study of the Child

Volume Thirty-two

edited by Ruth S. Eissler, Anna Freud, Marianne Kris, Peter B. Neubauer, and Albert J. Solnit

"The standard reference work for teaching and research in child analysis."—*Bulletin of the Menninger Clinic* $22.50

Thought, Consciousness, and Reality

Psychiatry and the Humanities, Volume 2

edited by Joseph H. Smith

This second volume to be published under the auspices of the Forum on Psychiatry and the Humanities of the Washington School of Psychiatry takes up major themes in psychoanalysis and philosophy: the influence of reason on action; the relation of language, dreams, and memory to thought; contemporary solutions to the problems of ambiguity and paradox; and the effect of the "psychic world" and "psychic freedom" on the concepts of meaning and truth. $15.00

Freud and Philosophy

An Essay on Interpretation by Paul Ricoeur

translated by Denis Savage

"Paul Ricoeur . . . has done a study that is all too rare these days, in which one intellect comes to grips with another, in which a scholar devotes himself to a thoughtful, searching, and comprehensive study of a genius. . . . The final result is a unique survey of the panorama of Freudian thought by an observer who, although starting from outside, succeeds in penetrating to its core."
—*American Journal of Psychiatry* Cloth $22.50 Paper $6.95

Yale University Press New Haven and London

in clinically significant depression...

penetrating the symptom barrier to productive psychotherapy

symptoms often interfere with therapy

In clinically significant depression, the patient often becomes barricaded behind his own symptoms during psychotherapy. Because these symptoms can be so sharply defined and somatic in expression, he may reject the fact that they are psychic in origin. Sleep disturbance, gastrointestinal complaints, anorexia, chronic fatigue, and other psychosomatic symptoms may so preoccupy—or overwhelm—the depressed patient that truly productive therapeutic sessions are difficult to achieve. Instead of being able to concentrate on the core emotional problems of the depression itself, he may for example go on at length about how broken his sleep is or keep reiterating (while the therapeutic hour slips by) how physically miserable he feels.

ELAVIL®
(AMITRIPTYLINE HCl, MSD)
to help penetrate the symptom barrier in depression requiring medication

ELAVIL, a highly effective tricyclic antidepressant, will often alleviate these symptoms. With the help of ELAVIL, sleep disturbance—so common in clinically depressed patients and often the symptom that distresses them most—as

well as other "barrier symptoms" may be lessened to the point where they no longer come between you and the patient.

psychotherapy takes direction

As these preoccupying complaints are lifted, psychotherapy sessions can become more productive. Patients are enabled to respond more fruitfully during therapeutic hours and to resume or pursue more efficiently the necessary activities in their personal lives.

meeting therapeutic goals

And as the antidepressant activity of ELAVIL (Amitriptyline HCl, MSD) takes hold, it helps relieve the depressive condition itself. Sometimes only a minimum of actual psychotherapy is required. The patient may experience a more rapid recovery—while you conserve valuable time.

Prescribe ELAVIL then, to help lighten the patient's burden in depression—and yours in its management.

ELAVIL should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Hospitalize as soon as possible any patient suspected of having taken an overdose.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, and 150 mg
INJECTION: 10 mg per ml

ELAVIL®
(AMITRIPTYLINE HCl | MSD)
an antidepressant with an anxiety-reducing sedative component to its action

addendum

To further simplify once-daily therapy for many depressed patients

Tablets

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

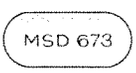
ONE TABLET, ONCE DAILY

—an appropriate way to prescribe for many depressed adult outpatients. Because of its simplicity, this regimen helps improve patient compliance. Of course, ELAVIL may also be prescribed in divided daily doses.

ONCE-DAILY DOSAGE SCHEDULE FOR ADULT OUTPATIENTS:

A single 75-mg tablet
Usual starting dosage

A single 100-mg tablet
Maximum starting dosage



A single 50-mg tablet
Minimum starting dosage

Dosage may be increased by 25 or 50 mg as necessary until a total of 150 mg per day is reached.

A single 150-mg tablet
Maximum daily dosage

ELAVIL MAY ALSO BE PRESCRIBED IN DIVIDED DAILY DOSES

The 25-mg tablet

This strength may prove useful when therapy is initiated with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime dose.

The 10-mg tablet

This strength may prove useful for patients who require lower doses, e.g., adolescent and elderly patients. For these patients who can not tolerate higher doses, 10 mg three times a day with 20 mg at bedtime may be satisfactory.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with amitriptyline HCl. Initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or a history of urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.
When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, increased intraocular pressure, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; tablets containing 150 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 30 and 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

CHARLES C THOMAS · PUBLISHER

BASIC APPROACHES TO GROUP PSYCHOTHERAPY AND GROUP COUNSELING (2nd Ed., 2nd Ptg.) *edited by* **George M. Gazda,** *Univ. of Georgia, Athens. (20 Contributors)* As with the First Edition, this Second Edition provides a convenient reference to basic theories for practitioners and students of group psychotherapy and group counseling. The amount of material covered in this new edition has increased markedly due to the growing popularity of the treatment and subsequent addition of several new theoretical positions.

Each chapter follows an outline that enables the reader to compare and contrast each position according to the following aspects: definition, theoretical foundation, related research, treatment goals, group selection and composition, group settings, group size, frequency and duration of group sessions, media employed, therapist/counselor qualifications, ethical considerations, limitations of the treatment, and suggested readings.

The fundamental psychotherapeutic positions summarized include psychodrama, psychoanalysis, existential group psychotherapy, behavioral group therapy, client-centered group therapy, reality therapy, transactional analysis, gestalt therapy, rational-emotive therapy, conjoint family therapy and group therapy with children. An eclectic position, a behavioral position and a teleoanalytic position are the three basic group counseling positions that are discussed. Each is represented by a leading proponent of the position, and references to more comprehensive sources for each theoretical model are cited.

This Second Edition also includes a revised chapter on the history and development of group psychotherapy and group counseling, a new chapter on the analysis of research and a new chapter with guidelines for ethical practice in group work.

Personnel and Guidance Journal cited this book as ". . . a readable, informative, and comprehensive collection of theoretical approaches to group work written by a distinguished group of contributors. . . . The major strength of the book lies in the fact that the writers do not simply present their theoretical positions; they push toward translating theory into practice, thereby providing a valuable resource book for students and practitioners of group work." *'77, 560 pp., 9 il., $16.75*

LEISURE COUNSELING: An Aspect of Leisure Education *edited by* **Arlin Epperson,** *Univ. of Missouri, Columbia;* **Peter A. Witt,** *Univ. of Ottawa, Ottawa, Ontario, Canada; and* **Gerald Hitzhusen,** *Univ. of Missouri, Columbia. (31 Contributors)* This book is designed to aid counselors, therapists, and park and recreation personnel in both institutional and community settings who wish to help their clients use free time more effectively. Personality and needs assessment, values clarification, and special problems of alcoholics, parolees, the mentally retarded, psychiatric patients, and retirees are examined. The focus is placed on the value of activities in achieving self-expression and self-actualization. Over 300 bibliographical references to authoritative literature in the field complement the text. *'77, 392 pp., 16 il., 22 tables, $18.00*

ACUTE GRIEF AND THE FUNERAL *edited by* **Vanderlyn R. Pine,** *State Univ. of New York, New Paltz;* **Austin H. Kutscher** *and* **David Peretz,** *both of Columbia Univ., New York City;* **Robert C. Slater,** *Univ. of Minnesota, Minneapolis;* **Robert DeBellis,** *Columbia Univ., New York City;* **Robert J. Volk,** *Burlington, Vermont; and* **Daniel J. Cherico,** *Columbia Univ., New York City. (47 Contributors)* This volume comprehensively describes the psychological and social impact of bereavement during the period of acute grief. Of particular interest are chapters on explaining death to children, the impact of social neglect on the elderly, and the roles of the psychiatrist, funeral director, educator and minister in giving counsel to the bereaved. *'76, 328 pp., 1 il., 26 tables, $16.50*

THE CLINICAL APPLICATION OF PROJECTIVE DRAWINGS (4th Ptg.) *edited by* **Emanuel F. Hammer,** *New York Univ., New York City. (14 Contributors)* A classic in this field, this book provides fundamentals of projective drawings, and goes on to considerations of differential diagnosis, appraisal of psychodynamics, conflict and defense, psychological resources as treatment potentials, and projective drawing usage in therapy. In addition to Buck's H-T-P Technique and Machover's Draw-A-Person Test, the book also includes the Draw-A-Family Procedure, Harrower's Unpleasant Concept Test, Kinget's Drawing Completion Test, and the Eight Card Redrawing Test. *'75, 688 pp., 360 il., $18.50*

THE BIOLOGICAL BASIS OF PERSONALITY (3rd Ptg.) *by* **H. J. Eysenck,** *Univ. of London, London, England.* The author proposes a descriptive and causal model of human personality which is consonant with current concepts in experimental psychology. The laws of behavior as they are affected by individual differences are reduced to the interplay of two dimensions, one embodying emotionality, neuroticism or instability, the other introversion-extroversion. Through psychometric studies and factor analysis, the author evolves basic dimensions of personality, rational methods of measurement, and the relationship between these dimensions and susceptibility to conditioning, disease patterns and drug response. He also probes for the biological causes underlying emotion, excitation, and inhibition. *'77, 420 pp., 134 il., 12 tables, $18.50*

RAPE: Offenders and Their Victims (2nd Ptg.) *by* **John M. Macdonald,** *Univ. of Colorado, Denver. Chapter by* **Hunter S. Thompson.** Provided in this book is a study in depth from the viewpoint of the offender, his victim, the physician, psychiatrist, police officer, and lawyer. Why do men commit this crime? What are their methods of committing the crime? How do they select their victims? What steps can a woman take to protect herself? These and many other aspects are reviewed, including homicide and rape and the incidence of pregnancy and venereal disease following. Special attention is paid to the psychology of the offender, criminal investigation, and the problem of false accusations of rape. *'75, 360 pp. (6 3/4 x 9 3/4), 6 tables, $14.50*

ART AND HUMAN EMOTIONS *by* **Egon Weiner,** *Chicago Art Institute, Chicago. Foreword by* **Jules H. Masserman.** This collection of lectures was presented to stimulate interest in and promote understanding of modern art and its emotional impact. The author opens doors to the knowledge of art and its meaning, and communicates his ideas which encompass a wide range of experience based on many years of traveling and working as an artist, teacher and lecturer. Emotional perception of subjective meanings and poetic interrelationships is discussed along with such topics as modern sculpture, inner and outer beauty in art, underlying motivations for artistic creation, the unattractive side of man as portrayed in art, symbolism in art and art education. *'75, 104 pp., 6 il., $6.75*

"Now Andy's classmates laugh

...with him, not at him"

Today, direct coaching in appropriate social interaction, role playing, and encounter techniques are being used to help hyperactive children overcome disruptive social behavior patterns that often cause them to become objects of ridicule to their peers.

Ritalin, when indicated, can also play a useful role in this respect, as improving social interaction in the MBD child often involves reducing hyperactivity. Indeed, as one investigator[1] has reported, with Ritalin therapy, the MBD child can be less aggressive, less impulsive, and better able to interact with his peers.

Other studies also report improved social behavior of MBD children on Ritalin.[2,3]

A drug of choice when treatment of MBD is indicated,[4,5] controlled studies and clinical experience have demonstrated the ability of Ritalin to effectively reduce hyperactivity,[1,2] distractibility,[1,3] and disorganized behavior[1,3,6-8] in the MBD child.

And these symptomatic improvements achieved with Ritalin often result in the child being more responsive to the nonpharmacological measures of the MBD management team.[8]

Although side effects – insomnia and appetite loss – are occasionally seen with Ritalin, they are less frequent or severe than with dextroamphetamine.[4,10]

Therapy with Ritalin should be undertaken only after a medical diagnosis of MBD has been made. Dosage should be periodically interrupted. Often these interruptions reveal some "stabilization" in the child's behavior even without medication. In some MBD children they permit a reduction in dosage and eventual discontinuance of drug therapy.

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Symptoms of visual disturbances have been encountered in rare cases. Difficulties with accommodation and blurring of vision have been reported.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over).

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-Pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

REMOVE THE MASK OF SCHIZOPHRENIC SYMPTOMS

'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY, AGITATION AND OTHER SCHIZOPHRENIC SYMPTOMS.

A FIRST CHOICE FOR THERAPY, 'STELAZINE' ALSO APPEARS TO HAVE AN ACTIVATING EFFECT WHICH IS ESPECIALLY USEFUL IN WITHDRAWN, APATHETIC OR DETACHED PATIENTS.

- EFFECTIVELY CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences — National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudoparkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only), 10 mg./ml.

brand of **STELAZINE®** Tablets: 5 and 10 mg.

TRIFLUOPERAZINE HCl

A FIRST CHOICE FOR THERAPY

Warner/Chilcott Introduces

VERSTRAN®
(prazepam) C IV

A new addition for the treatment of anxiety

Verstran® (prazepam) provides the antianxiety effectiveness you expect from a benzodiazepine —plus dosage versatility

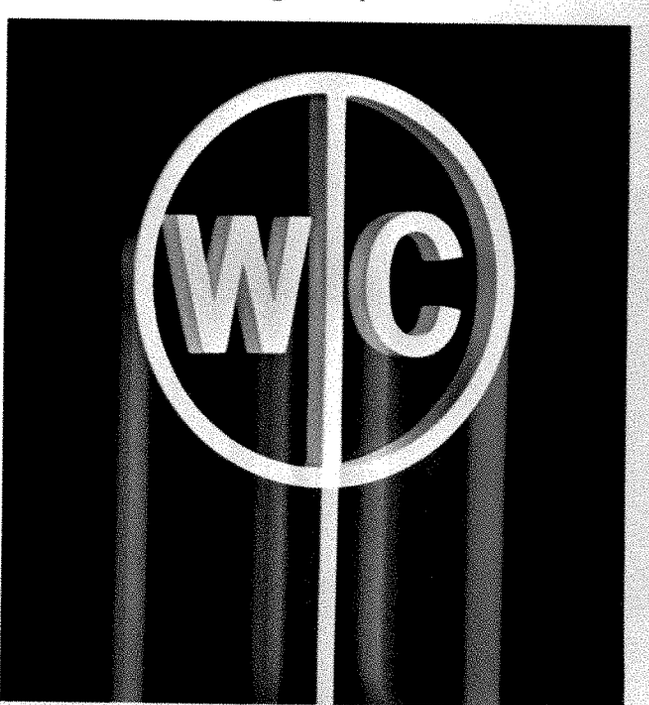
New Verstran
Reduces symptoms of anxiety–whether psychic or somatic in origin.

New Verstran
Provides the simplicity of a single scored 10 mg tablet to facilitate titration.

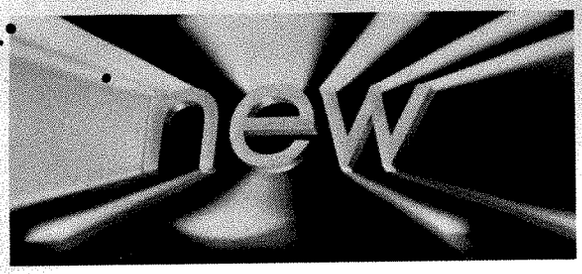
Plus 2 dosage options

Option 1:

New Verstran can be administered in a daily divided dose.
Starting with 10 mg b.i.d., dosage may be titrated gradually within a range of 20 to 60 mg per day in accordance with response.



Option 2:



New Verstran can be taken once a day at bedtime.
The usual starting dose for this regimen is 20 mg (two 10 mg tablets). Optimum dosage usually ranges from 20 to 40 mg daily.

*Data on file, Warner/Chilcott Medical Department.
†Number of patients cited represents those evaluated at final observation.

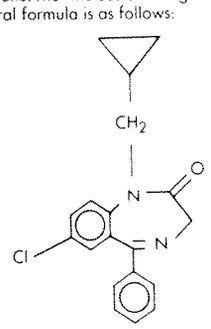
• Please see last page of this advertisement for full product information.

New Verstran
Eleven double-blind studies totaling 560 patients were conducted using b.i.d. and h.s. dosage regimens. Global Improvement Ratings, made at week 2, 3, or 4 for the b.i.d. dose, and at week 3 or 4 for the h.s. dose, confirmed the clinical efficacy of Verstran in both dosage options.*†

VERSTRAN®
(prazepam) Ⓒ IV

■ **New Verstran**
Effective for the symptomatic relief of a wide range of anxiety conditions—whether psychic or somatic in origin.

■ **New Verstran**
The simplicity of a single scored 10 mg tablet.



■ **New Verstran**
The versatility of fully effective divided daily or single nighttime dosage.

■ **New Verstran**
Side effects are characteristic of benzodiazepine drugs.*

Verstran* (prazepam) Ⓒ IV

Caution: Federal law prohibits dispensing without prescription.

Description: Verstran (prazepam), a benzodiazepine derivative, is identified chemically as 7-chloro-1-(cyclopropylmethyl)-1,3-dihydro-5-phenyl-2H-1, 4-benzodiazepin-2-one. The molecular weight is 324.8 and the structural formula is as follows:

Clinical Pharmacology: Studies in normal subjects have shown that Verstran (prazepam) has depressant effects on the central nervous system. Oral administration of single doses as high as 60 mg and divided doses up to 100 mg t.i.d. (300 mg total daily dose) were without toxic effects.

Single oral doses of Verstran in normal subjects produced peak blood levels at 6 hours postadministration, with significant amounts still present after 48 hours. Verstran was slowly absorbed over a prolonged period, rather constant blood levels were maintained, and excretion was prolonged. The mean half-life of prazepam measured in subjects given 10 mg t.i.d. for one week was 63 (± 15 s.d.) hours before and 70 (± 10 s.d.) hours after multiple dosing—a nonsignificant difference. Human metabolism studies showed that prior to elimination from the body, prazepam is metabolized in large part to 3-hydroxyprazepam and oxazepam.

Indications: Verstran (prazepam) is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

Contraindications: Verstran (prazepam) is contraindicated in patients with a known sensitivity to the drug and in those with acute narrow angle glaucoma.

Warnings: Verstran (prazepam) is not recommended in psychotic states and in those psychiatric disorders in which anxiety is not a prominent feature.

Patients taking Verstran should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery, including motor vehicles.

Because Verstran has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, including phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. The effects of alcohol may also be increased.

Physical and Psychological Dependence: Withdrawal symptoms similar in character to those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepine drugs. These symptoms include convulsions, tremor, abdominal and muscle cramps, vomiting and sweating. Addiction-prone individuals, such as drug addicts and alcoholics, should be under careful surveillance when receiving benzodiazepines because of the predisposition of such patients to habituation and dependence.

Precautions:
Use in Pregnancy and Lactation:
An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. Verstran (prazepam) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug. In view of their molecular size, Verstran and its metabolites are probably excreted in human milk. Therefore, this drug should not be given to nursing mothers.

In those patients in whom a degree of depression accompanies the anxiety, suicidal tendencies may be present, and protective measures may be required. The least amount of drug that is feasible should be available to the patient at any one time.

Patients taking Verstran for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed. Hepatomegaly and cholestasis were observed in chronic toxicity studies in rats and dogs.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

Pediatric Use:
Safety and effectiveness in patients below the age of 18 have not been established.

Adverse Reactions: The side effects most frequently reported during double-blind placebo-controlled trials employing a typical 30 mg divided total daily dose and the percent incidence in the Verstran (prazepam) group were: fatigue (11.6%), dizziness (8.7%), weakness (7.7%), drowsiness (6.8%), lightheadedness (6.8%), and ataxia (5.0%). Less frequently reported were: headache, confusion, tremor, vivid dreams, slurred speech, palpitation, stimulation, dry mouth, diaphoresis, and various gastrointestinal complaints. Other side effects included: pruritus, transient skin rashes, swelling of feet, joint pains, various genitourinary complaints, blurred vision, and syncope. Single nightly dose, controlled trials of variable dosages showed a dose-related incidence of these same side effects. Transient and reversible aberrations of liver function tests have been reported, as have slight decreases in blood pressure and increases in body weight.

These findings are characteristic of benzodiazepine drugs.

Overdosage: As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

If vomiting has not occurred spontaneously, it should be induced. Immediate gastric lavage is also recommended. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though unlikely, may be controlled with Levophed® (levarterenol bitartrate) or Aramine® (metaraminol bitartrate). Caffeine and Sodium Benzoate Injection, USP, may be used to counteract central nervous system depressant effects.

Dosage and Administration: Verstran (prazepam) is administered orally in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 20 to 60 mg daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a divided daily dose of 10 mg to 15 mg. (See Precautions.)

Prazepam may also be administered as a single dose daily at bedtime. The recommended starting nightly dose is 20 mg. The response of the patient to several days' treatment will permit the physician to adjust the dose upward or, occasionally, downward to maximize antianxiety effect with a minimum of daytime drowsiness. The optimum dosage will usually range from 20 to 40 mg.

Drug Interactions: If Verstran (prazepam) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monamine oxidase inhibitors or other antidepressants.

If Verstran is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

How Supplied: Verstran (prazepam) 10 mg light blue, scored tablets in bottles of 100 (N 0047-0276-51).

STORE BETWEEN 59°-86° F (15°-30° C).

*Please see this page for warnings, precautions and adverse reactions.

The American Psychiatric Association announces publication of two volumes reporting the Conference on Education of Psychiatrists

held at Lake of the Ozarks, Missouri, June 9-15, 1975. Organized by the A.P.A. in cooperation with the American Academy of Child Psychiatry, the American Association of Chairmen of Departments of Psychiatry, and the American Association of Directors of Psychiatric Residency Training.

1. PSYCHIATRIC EDUCATION: PROLOGUE TO THE 1980's, Library Bound, 544 pages, $15.00.

This is a substantive, highly readable, report of the Conference, written by Anne H. Rosenfeld with an Editorial Board comprising: Ewald W. Busse, M.D., Chairperson of the Conference, Walter E. Barton, M.D., Bernard Holland, M.D., Donna Norris, M.D., Melvin Sabshin, M.D., Jeanne Spurlock, M.D., and Robert L. Robinson, M.A. (Staff Consultant).

The volume contains ten chapters covering the topical structure of the Conference: Goals and Values; Competence, Evaluation, and Quality Control; The Resident; Faculty; Educational Methods: Means in the Service of Ends; The Program Environment; Research; The Economics of Residency Training; Psychiatry in Its Social Context; and Retrospect and Prospect. It also contains nine appendices describing the organization of the Conference and its participants, together with selected model programs and related informational materials of value.

2. THE WORKING PAPERS OF THE 1975 CONFERENCE ON EDUCATION OF PSYCHIATRISTS Paper bound, 432 pages, $12.50.

Sixty two leading psychiatric educators served on seven preparatory commissions, one for each of seven topic areas, and prepared advance working papers as a basis for Conference deliberations. The topics and Commission Chairpersons were: Social Issues and Needs (James N. Sussex, M.D.); Goals and Objectives (Morton F. Reiser, M.D.); The Resident (David R. Hawkins, M.D.); Content, Methodology, Faculty and Environment (Milton Greenblatt, M.D.); Research (Daniel X. Freedman, M.D.); Economics (Herzl Spiro, M.D.); Evaluation and Quality Control (Eric Pfeiffer, M.D.). The Chairpersons, together with the Conference Chairperson, served as the Editorial Board for this volume.

Papers commenting on the reports of the commissions, published here for the first time, were presented at the Conference by Melvin Sabshin, M.D., Eugene B. Brody, M.D., Jeanne Spurlock, M.D., Jack R. Ewalt, M.D., Robert J. Stoller, M.D., James R. Comer, M.D., and Bernard Holland, M.D.

CLEARING OF DEPRESSION
ANTIDEPRESSANT EFFECTIVENESS... with convenient once-a-day h.s. dosage*
SINEQUAN®
(DOXEPIN HCl)
75-mg CAPSULE
Also available: 100-mg, 50-mg, 25-mg, 10-mg CAPSULES and ORAL CONCENTRATE 10 mg/ml, in 120-ml (4-oz) bottles
*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.
See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions.

IN THE TREATMENT OF CLINICAL DEPRESSION—

SINEQUAN® 75 mg (DOXEPIN HCl) CAPSULE

PROVIDES ANTIDEPRESSANT EFFECTIVENESS

IN ADDITION TO OTHER, OFTEN BENEFICIAL, PROPERTIES...

CONVENIENT ONCE-A-DAY h.s. DOSAGE

which may increase patient compliance. The total daily dosage, up to 150 mg per day, may be given on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and early-morning awakening often associated with depression.

MARKED ANTIANXIETY ACTIVITY

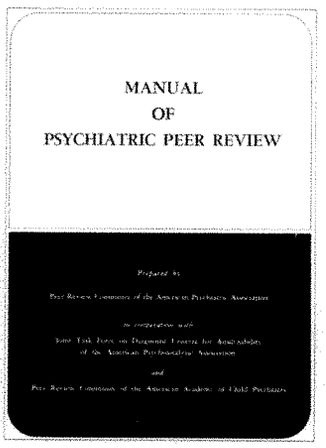
to help alleviate the anxiety which often accompanies clinical depression.

WELL TOLERATED

At doses up to 150 mg per day, Sinequan does not generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have occasionally been reported. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

EXTENDED RANGE OF DOSAGE STRENGTHS

for flexibility in individualizing therapy.



BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate
Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. These disorders should be ruled out, particularly in older patients. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.
Warnings. The once-a-day dosage regimen of SINEQUAN in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.
Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.
Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.
Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.
MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.
Usage with Alcohol: It should be borne in mind that alcohol ingestion may increase the danger inherent in any intentional or unintentional SINEQUAN overdosage. This is especially important in patients who may use alcohol excessively.
Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.
Patients should also be cautioned that their response to alcohol may be potentiated.
Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.
Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.
Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.
Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.
Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.
Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.
Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.
Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.
Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)
Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.
Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.
Dosage and Administration. For most patients with illness of mild to moderate severity, a starting dose of 25 mg t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg/day to 150 mg/day.
In more severely ill patients an initial dose of 50 mg t.i.d. may be required with subsequent gradual increase to 300 mg/day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg/day.
In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg/day.
As an alternative regimen, the total daily dosage, up to 150 mg, may be given on a once-a-day schedule without loss of effectiveness. This dose may be given at bedtime.
Antianxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.
Overdosage.
A. Signs and Symptoms
1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.
2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias and tachycardias.
Also: urinary retention (bladder atony), decreased gastrointestinal motility (paralytic ileus) hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.
B. Management and Treatment
1. Mild: Observation and supportive therapy is all that is usually necessary.
2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressive supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions to prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbed. The use of activated charcoal has been recommended, as has been continuous gastric lavage with saline for 24 hours or more. An adequate airway should be established in comatose patients and assisted ventilation used if necessary. EKG monitoring may be required for several days since relapse after apparent recovery has been reported. Arrhythmias should be treated with the appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CNS symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intravenous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine is rapidly metabolized, the dosage should be repeated as required. Convulsions may respond to standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depression. Dialysis and forced diuresis generally are not of value in the management of overdosage due to high tissue and protein binding of SINEQUAN.
Supply. SINEQUAN is available as capsules containing doxepin HCl equivalent to 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). SINEQUAN (doxepin HCl) 25 mg and 50 mg are also available in bottles of 5000. SINEQUAN Oral Concentrate (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrated at 5 mg, 10 mg, 15 mg, 20 mg, and 25 mg. Each ml contains doxepin HCl equivalent to 10 mg doxepin. Just prior to administration, SINEQUAN Oral Concentrate should be diluted with approximately 120 ml of water, whole or skimmed milk, or orange, grapefruit, tomato, prune or pineapple juice. SINEQUAN Oral Concentrate is not physically compatible with a number of carbonated beverages. For those patients requiring antidepressant therapy who are on methadone maintenance, SINEQUAN Oral Concentrate and methadone syrup can be mixed together with Gatorade®, lemonade, orange juice, sugar water, Tang®, or water; but not with grape juice. Preparation and storage of bulk dilutions is not recommended.
More detailed professional information available on request.

MANUAL OF PSYCHIATRIC PEER REVIEW

by the Peer Review Committee of the American Psychiatric Association, Donald G. Langsley, M.D., Chairperson in cooperation with the Joint Task Force on Diagnostic Criteria for Analyzability of the American Psychoanalytic Association, William Offenkrantz, M.D., Chairperson, and the Peer Review Committee of the American Academy of Child Psychiatry. Larry B. Silver, M.D., Chairperson.

"This Manual provides a set of guidelines for district branches of APA and their peer review committees which should be adapted and modified in terms of local criteria, standards, and practices. The guidelines are not intended to be hard and fast rules. They are screening criteria, and not regulations to control practice. They are so designed that they can be utilized by non-physicians to identify those cases that can profitably be reviewed by psychiatrists serving on peer review committees. This document should be viewed as transitional, subject to revision as experience is gained, and continually updated in response to advances in psychiatric knowledge and changes in patterns of practice. . . . The application of these standards, and refinement through experience must rest with the peer review committees of district branches. . . . It should help them to move ahead in the development of a peer review for American psychiatry."

Robert W. Gibson, M.D.
President

Part I titled PSYCHIATRIC PEER REVIEW contains sections on Basic Relationships and Responsibilities, Appointment of Peer Review Committees, Funding, Operations and Procedures, Medical Care Evaluation Studies, Appeals Processes, Special Problems, Confidentiality, Educational Aspects, Medical Ethics, Advocacy, Interdisciplinary Aspects, with Appendices on Model Screening Format for Inpatient Treatment for Alcoholism, Model Screening Format for Outpatient Treatment, Sample Form for Requesting Extension of Office Treatment, Claims Review Guidelines Suggestions, APA Position Papers on Peer Review, Bibliography.

Part II titled PSYCHOANALYTIC PEER REVIEW has sections on Steps in Peer Review for Psychoanalysis, Guidelines for Model Criteria Sets, Pilot Application of Guidelines for Model Criteria Sets, Sample Peer Review Form, Sample data from Pilot Applications of Guidelines, and Glossary of Terms Used.

Part III titled PEER REVIEW AND CHILD PSYCHIATRY contains sections of Special Considerations, Legal Rights of Children, Issue of Confidentiality, Conclusions, References, and Appendices on Model Screen Criteria Format for Intermediate Care, for Acute Care in a Short Stay Facilities, and for Partial Hospitalization, Outpatient Diagnostic Evaluation Procedures, and Outpatient Treatment for Children and Adolescents.

Published by the American Psychiatric Association, Washington, D.C., September 1976. 114 pages. Spiral binding. Single copies, $6.00. For orders of 10 or more, $5.00 per copy.

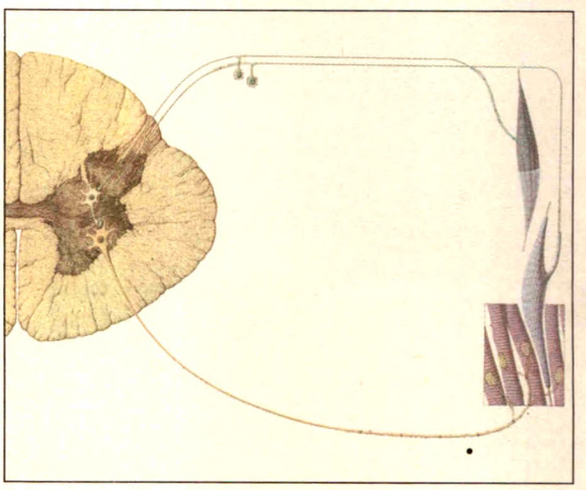
MIND & MUSCLE...



ONLY VALIUM (diazepam) HAS THESE TWO DISTINCT EFFECTS...

MIND: PSYCHOTHERAPEUTIC

Valium is useful for the relief of undue psychic tension and anxiety whether seen alone or associated with organic or functional disorders, or with secondary depressive symptoms. Valium provides a quality of response you know, want and trust. A response which has a pronounced effect on the somatic symptoms of anxiety.

MUSCLE: SKELETAL MUSCLE RELAXANT

Preliminary studies in both animals and humans have suggested that Valium (diazepam) may also work at the spinal level by enhancing presynaptic inhibition, a mechanism believed to diminish spasm in skeletal muscle. Clinically, adjunctive Valium has significant skeletal muscle relaxant properties.

VALIUM® (diazepam) IV

2-MG, 5-MG, 10-MG SCORED TABLETS

FOR THE RESPONSE YOU KNOW, WANT AND TRUST

Before prescribing, please see following page for a summary of product information.

ROCHE

VALIUM®
(diazepam)

Before prescribing, please consult complete product information, a summary of which follows:

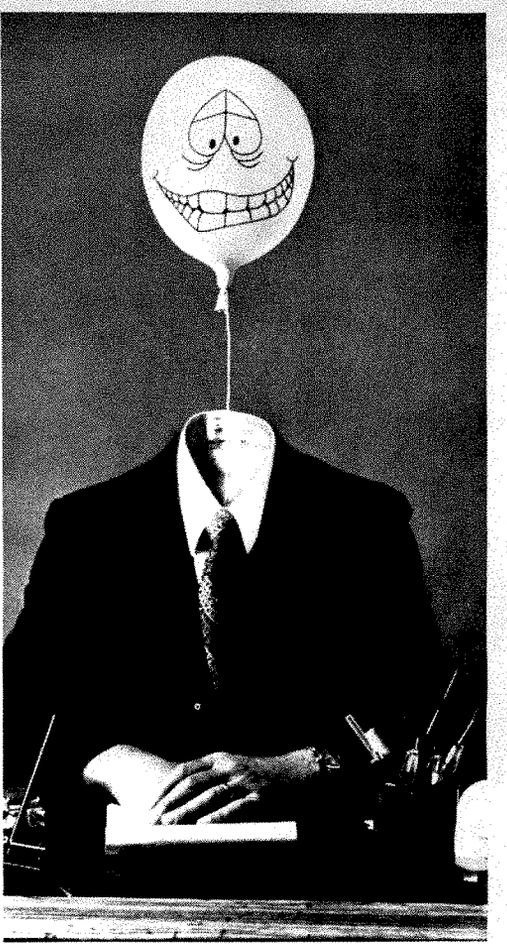
Indications: Tension and anxiety states, somatic complaints which are concomitants of emotional factors, psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation, symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders, athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

***Usage in Pregnancy:* Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.



Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

High Blood Pressure?

Only your doctor can tell. Like more than 10 million other Americans, you could have high blood pressure and not know it until it leads to stroke, heart or kidney failure. It has no special symptoms and often gives no warning. But your doctor can detect high blood pressure (he may call it hypertension) and usually control it. So see your doctor . . . and follow his orders.

In the hospitalized patient...
For Brief Summary, please see following page.
SANDOZ
SAN 6-640R

ANTIPSYCHOTIC EFFICACY... INFREQUENT EXTRAPYRAMIDAL SYMPTOMS

Antipsychotic medication should not interfere with the patient's ability to participate in your total therapeutic program. That is why Mellaril (thioridazine) is an excellent choice. It is highly effective, and although extrapyramidal symptoms are characteristic of this class of drug, with Mellaril (thioridazine) extrapyramidal stimulation—notably pseudoparkinsonism—is infrequent. Adding an antiparkinsonian agent—which can cause its own side effects—can usually be avoided.

Mellaril (thioridazine) is not habituating and usually does not cause euphoria or undue sedation. (But, warn patients about undertaking activities requiring complete mental alertness.) And Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

MELLARIL® (THIORIDAZINE)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP

©1977 Sandoz, Inc.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Neurobiological Origins of Psychoanalytic Dream Theory

BY ROBERT W. MCCARLEY, M.D., AND J. ALLAN HOBSON, M.D.

Freud built his model of the mind and his hypotheses about dreaming directly on the structure of his neurobiological model of the brain, which was developed in the "Project for a Scientific Psychology," written in 1895. Among the concepts modeled in this work were ego, somatic drives as motivationally critical, cathexes of psychic energy, wish fulfillment, and primary and secondary process. From the vantage point of more than 80 years later, the authors indicate the areas in which many of Freud's neurobiological assumptions are inaccurate. Revisions are needed in the neurobiologically derived psychoanalytic concepts, especially those of Freud's wish fulfillment-disguise theory of dreams.

THE MOST celebrated theory of dreams is that of Sigmund Freud. Today Freud's idea that certain memories actually *cause* dreams is so widely accepted that it constitutes a major article of belief in American popular and literary culture, not to mention its pervasive influence within clinical psychiatry.

Less well appreciated is the extent of Freud's fascination with biology and the extent to which Freud's psychological theories, including those of "The Interpretation of Dreams" (1, 2), are the offspring of his long experience in neurobiology. In this paper we will examine the ghosts of antique neurobiology that still haunt Freud's dream theory, attempt to refurbish the neurobiology of sleep in accord with today's understanding, and then examine the consequences for psychoanalytic theory in general and dream theory in particular.

The two principal divisions of this paper will develop aspects of this theme. We shall first discuss the neurobiology of the 1890s to allow an understanding of what was known and in vogue when Freud was working on a model of the brain. We shall then show that Freud's psychology was rooted in his neurobiology, rooted deeply in an explicit model of the brain, and comment on what modern sleep neurophysiology may have to say about the accuracy of Freud's theories. A related article (3) will explore the extent to which an alternative, but still biologically oriented, theory of dream experience can be developed.

In both papers we will use the phrase "mind-body isomorphism" to describe a particular conceptualization of the relationship between body and mind, one that encompasses the most fundamental assumption of Freud, and, indeed, of many theorists of the 1890s. Freud believed that the *same* rules of description and functioning might be applied to both body and mind and that both had the same structures, the same basic operating principles, and the same rules of energy transfer, or dynamics. Whether one talked about physiological or psychological data or concepts seemed to be a matter of convenience and ease, for there were simple rules for mapping the concepts and operations of one domain onto the other.

We indicate this hypothesis of similarity by the term "isomorphism," which means literally "of the same form." It also has a quite exact usage in mathematics to indicate when there are precise rules for conversion between two logical structures or algebraic systems composed of objects and operations upon these objects (4). Although we think the precise aspects of the isomorphism concept may ultimately prove useful, this is not the place to discuss its possible direct applicability, and in this paper we will use the term in a less exact sense.

The term "isomorphism" will also serve to indicate the extent to which Freud believed that his model of

Based on a paper presented by Dr. McCarley at the 16th annual meeting of the Association for the Psychophysiological Study of Sleep, Cincinnati, Ohio, June 2–6, 1976.

Dr. McCarley is Assistant Professor of Psychiatry and Dr. Hobson is Associate Professor of Psychiatry, Harvard Medical School, Boston, Mass. The authors wish to express their appreciation to Drs. John Nemiah and John Nelson for their helpful comments on the manuscript.

the brain could lead to inferences about a model of the mind and vice versa. We view Freud's approach, the search for linkages between brain and mind models and data, as important and fruitful; we ourselves are concerned with such a search and use modern knowledge of neuronal and dream physiology as a basis for connections with dream psychology.

THE NEUROBIOLOGY OF THE 1890s

There are historical parallels between the great explosion of knowledge occurring in the field of neurobiology today and in the 1890s. In 1889 Santiago Ramon y Cajal made a victorious anabasis to Berlin where he presented to the leading scientists of the German-speaking world his dogma that the brain is composed of individual cells that are separated from each other and that the brain is not a reticulum or net as Golgi and others had believed (5). Cajal's exquisite materials persuaded even the mighty Kölliker, and the Germanic establishment gave the final stamp of accord in 1891 when Waldeyer spoke favorably of the "neuron theory." The study of cells and neurons was what was new and exciting, even though knowledge of pathways and functional localization was also quite advanced and certainly beyond that of most of today's first-year medical students. For example, to anticipate ourselves a bit, Freud had a certain fame as the neurologist whose powers of lesion localization were so sure that a pathological report was superfluous.

Compared with the neuroanatomy, the neurophysiology of the 1890s was not so far advanced, and we shall see that misconceptions in that area were to bedevil Freud's theory. At that time the precise role of electrical forces in nerve cells was unknown, although the knowledge of electrical changes associated with reflex conduction had made it apparent that electrical phenomena were important. It was Freud's misfortune to develop his theory of neuronal discharge and of the energy economy of the brain at this point of physiological uncertainty about the electrical and functional aspects of neurons.

A most important component of the spirit of that time was the sense of excitement. Old dogmas were falling, new edifices were being erected—in politics, the arts, biology, and physics. In biology, vitalism was being crushed by the new armamentarium of chemistry and physics. Biologists of Freud's generation were marked by two traits. First, they were loath to be mystical in any way; hard-nosed materialism—scientific method—was their credo and their weapon against the still lingering forces of vitalism. Yet they also had an audacity, an abundance of hope and faith in the new scientific method and the excitement of believing themselves on the verge of being scientifically able to describe that most difficult and elusive object of all, the human mind.

An extremely valuable source of information about the state of physiological and anatomical knowledge in Vienna in the 1890s comes from a book by Sigmund Exner. Exner was a co-worker of Freud's in the day when both were neurobiologists (6), and Exner went on to become the head of the department of physiology at the Royal University of Vienna. In scientific circles Exner was best known for his studies on reflexes and reflex conduction velocity (7, 8). Yet he also wrote the book *A Sketch of a Physiological Explanation of Psychic Events* (9). His book was published in 1894, just one year before the essence of Freud's theory of dreams was developed, and its title well conveys the audacity of that time, the soaring hope of a physiology of the mind.

Exner explained what he wanted to do in the introduction to the book, which was, appropriately for one speaking in both physiological and psychological tongues, completed on Pentecostal Sunday. With an eye on the vitalism of the past he wrote, "A path has been broken toward [the] conviction that life processes can be explained on the basis of chemical and physical processes. . . ." Looking toward the present and future and in a striking parallel to Freud's ambition, he noted that "the attempt to explain psychic events forms my assignment in life." As well as letting us see what was hoped for (the union of physiology and psychology), the book is most valuable from a documentary point of view because it allows us to scan the kind of physiological data and theory present in Vienna just before Freud's "The Interpretation of Dreams."

Exner used one of his own reflex experiments to illustrate the important concept of *Bahnung*, or, as Sherrington (8) translated this word, "facilitation." At certain stimulus intensities, neither a paw stimulus alone nor a cerebral cortical electrical stimulus alone will elicit the response of a paw twitch. However, when the two stimuli occur in close temporal contiguity a response results. The inference was that each stimulus served to facilitate the other and that a pathway (*Bahn* in German) had been formed so that the excitation from each stimulus could sum and produce a response. Freud was to make extensive use of this concept, as he did of the notion of temporal summation, or facilitation from repeated stimuli. Exner committed himself to the neuron theory and even went so far as to postulate that inhibition was an active mechanism served by its own neural pathways (9, p. 306; 10). This important but subtle concept of active inhibitory pathways is one that was not posited by many early neural theorists, including Freud (11). Exner's book may well have served as a stimulus for Freud's own attempts at a mind-body integration by combining his neurobiological training with his newly developing interest in the psyche.

FREUD'S "PROJECT"

Freud was a co-worker of Exner's at the University Physiological Institute in Vienna and is cited in Exner's work for his histological studies. Breuer, Freud's

collaborator in "Studies on Hysteria" (12), was Exner's family physician (13). Because of these relationships and interests it is quite likely that Freud knew about Exner's 1894 book, and Freud himself seems to have indicated that this was the case (14).

Freud spent most of his early career working in neurobiology. In 1876, at age 20, he began work in the University Physiological Institute. He obtained his doctorate in medicine in 1881, and in 1882, at age 26, he terminated his connection with the institute after 6 years of research work. Amacher (6) has examined the strong influence on Freud of the neurological doctrines and concepts of his teacher at the institute, Brücke, and of Meynert, Freud's teacher while Freud was a resident in the department of neurological diseases in 1884 (age 28) at Vienna General Hospital. In 1885, at age 29 and with a decade of training in neurobiology and neurology in Vienna behind him, Freud left the Vienna General Hospital and by 1886 had set up a practice as a neuropathologist. He retained an active interest in physiology, as evinced by his 1888 article in a medical encyclopedia on the brain (15) and by his 1891 volume on aphasia (16). Although he was developing interests in hypnosis, catharsis, and hysteria, he was still very much in the Viennese tradition of *Nervenartz* in 1895 when, at the age of 39, he wrote the document of particular interest to us.

This is the "Project for a Scientific Psychology" (14), or as we shall call it, the "Project." At the beginning, Freud told what he wished to do: "The intention is to furnish a psychology that shall be a natural science." Freud attempted to show the brain mechanisms of complex psychic phenomena, to develop a physiology of the mind. He occupied himself off and on with the "Project" from April 1895 to January 1896 and completed Part I, the part that is most important for our discussion, by the end of September 1895. This was a highly active period in Freud's life; he was also working out the ideas for "The Interpretation of Dreams" (1, 2), which he noted was essentially complete by the beginning of 1896. Indeed, Freud worked on both the "Project" and "The Interpretation of Dreams" during the summer of 1895 and it was at his summer house that he fancied later seeing this inscription: "In This House on July 24th, 1895, the Secret of Dreams was Revealed to Dr. Sigm. Freud." Freud described the "Irma dream" as the important catalyst, and this dream is referred to in both the "Project" and in "The Interpretation of Dreams."

There are several compelling reasons for focusing on the "Project"; the most important one is that the themes of the "Project" were the themes that would be dealt with throughout Freud's life. These ideas, derived directly from physiology, were the archaic mold for most of Freud's later theories of the mind. This is not to say that Freud's concepts were not clinically related. They were, but it must be remembered that what Freud was trying to do was to give a structure to the unconscious, by definition known only indirectly, and his ideas were strongly conditioned by what he knew from other sources, especially from his earlier work in neurobiology. This is particularly true for "The Interpretation of Dreams"; most of its theory was developed when Freud had analyzed only a *single* dream, his own "Irma dream" (1, 2, 14, 17).

Several writers have recognized and emphasized the close links between the neural model of the "Project" and the psychological model of Freud's later work. Jones, Freud's biographer, was strong in his affirmation of the "Project's" significance and documented this with a list of the 23 major topics of the "Project," 20 of which were to be discussed in detail in Freud's later writings (13). Strachey, Freud's translator and editor of the standard edition of his works in English, reported that the "Project," or rather its "invisible ghost, haunts the whole series of Freud's theoretical writings to the very end" (18). The contemporary psychoanalytic theorist, Holt, has used the "Project" as a basis of documentation of how "hidden biological assumptions . . . were retained . . . [in the] construction of an abstract psychological model" (19). Recently Pribram and Gill (20) have again emphasized that the "Project" contains, in their clearest form, the "explicit formulations and definitions of many central concepts and terms of that branch of psychoanalytic theory known as metapsychology, concepts and terms that Freud continued to use throughout his life."

For the reader whose introduction to Freud has been through the more clinically oriented papers, it is a great shock and revelation to read the "Project" since the embryos of most of Freud's major theoretical concepts are to be found here. Twenty years of concepts elaborated in clinical papers are collapsed into a few lines, and to add to the sense of wonder, they appear in a physiological paper. For the modern neurophysiologist the astonishment is of a different sort. So many of Freud's ideas about the function of neurons were simply and fundamentally wrong. We shall show that these erroneous physiological assumptions had important consequences for the formation of Freud's psychological theory.

The Elements of Freud's Model: The Neurons

In order to understand Freud's neural model it is first necessary to examine his conception of the constituent elements, the neurons, and the difficulties with many of his ideas that 80 succeeding years of neurophysiological research have made evident. The neurons in Freud's theory do appear structurally rather modern. They are discrete cells with points of contact between them, and Freud was quite correct in assuming some kind of structural specialization at the gaps between cell processes (which we call synapses). Physiology was the problem area, and Freud's principal ideas and the contrasting modern concepts about neurons can be grouped into four categories (see table 1).

1. *Neurons as serving for energy storage versus information transmission.* The modern view of neurons is that they are cells specialized for information trans-

TABLE 1
Contrasting Views of Neuronal Function

Concept	Freud's View	Modern View
Functional specialization of neuron.	Neuron as energy reservoir.	Neuron as signal element.
Mode of interaction of sensory neurons with external and somatic stimuli.	Energy conducted by neurons to the CNS.	Energy transduced by neurons.
Mode of neuronal activation.	"Passive" neurons: ultimate energy source, and stimulation to activity is always outside the CNS.	"Active" neurons: energy generated by neuronal metabolism with autochthonous regulation of neural activity.
Sign of neuronal interaction.	Excitation only.	Excitation *and* inhibition.

mission, for signaling. They use their own (metabolic) energy sources to maintain an electrical potential gradient between the outside and inside of the cell membrane (usually about −60 millivolts). A small lowering of the membrane potential sets into motion a positive feedback system leading to a "discharge" or complete depolarization of the membrane; only such "all or nothing" discharges propagating down the cell axon serve to communicate with distant cells by means of chemical transmitter release at the synapses.

The following tenets of modern electrophysiological theory contrast with Freud's ideas: 1) each cell generates its own "resting" polarization, 2) neurons influence each other by acting on this preexisting polarization, and 3) the actual amount of energy transfer between neurons needed to influence polarization and discharge frequency is quite small. These critical concepts remain valid even for other, more exotic forms of neuronal interaction, such as instances of electrical coupling and dendrodendritic synapses.

Freud, on the other hand, thought of neurons as passive energy reservoirs, able to be filled or "cathected" (*Besetzung*) with greater or lesser amounts of energy, with what he termed "nervous quantity" or *Qn*, as he abbreviated it. This stored energy, always derived from energy sources outside neurons, was passed on to other neurons in graded amounts. "Nervous quantity" is best thought of as electrical energy, although there were occasional uses of mechanical metaphors (energy of motion), as when Freud referred to neuronal "motion" or "vibration." This concept of neurons as passive reservoirs of energy derived elsewhere and of influencing other cells by passing on this energy is at variance with the modern notion of neurons as signaling elements. In electrical terms, Freud's energy dynamics would be modeled by "large signal analysis," the viewpoint appropriate to power supplies and transmission lines; the small amounts of energy involved in information transfer in the modern view suggest an analogy with "small signal analysis." Note that Freud's use of "discharge" was quite different from the modern meaning of a depolarization; for Freud it meant actual discharge of the quantity of nervous energy that was acquired, analogous to the discharge of a capacitor. It is, of course, not surprising that Freud was unable to guess the true nature of electrical forces in neurons since even the existence of the neuronal resting potential was not discovered until 1910.

2. *Neurons as conduits for energy transmission from outside into the CNS versus sensory receptor neurons as transducers*. The current neurophysiological conception of sensory receptor neurons is that they act as transducers, that is, they signal the presence of energy (e.g., light, sound, heat, and skin deformation) in the external world. They transduce this energy into a coded form of electrical signal. Similarly, from the internal world of the body, they transduce and signal information on joint angles, acceleration in space, distention of a viscus, and so forth. The important concept is that the signal indicates the presence of energy but does not conduct the energy itself into the CNS. An analogy is any physical transducer, such as a current meter, that signals the presence of current but does not itself conduct it.

In Freud's viewpoint neurons were characterized by an *actual transfer* of graded amounts of *Qn*, or nervous energy. It would be quite frightening to think of these neurons in one's periphery, for they would transmit the energy of, say, a lightning bolt directly into the CNS where this energy would have access to the whole pool of neurons. Freud used the term "excitation of neurons" (*Erregung*) to mean that they are *acquiring energy*, a notion very different from the modern concept that membrane potential is being altered in such a way as to increase the probability of discharge.

3. *Neurons as passive acceptors and donors of energy versus neurons as spontaneously active*. Freud held tenaciously to the idea of neurons as sources and sinks of energy ultimately derived from outside the brain; he on no occasion postulated that neurons had their own metabolic energy sources or that they formed self-regulatory networks. This assumption was of critical importance for Freud's neural model, and it led him to place the cause of dreaming outside the brain, since the ultimate sources of energy were also necessarily extracerebral. Dreams originated from somatic or external stimuli. This assumption further committed Freud to a reactive, essentially passive brain and to a model of the psyche that shared these characteristics. In sharply contrasting fact, the crucial biological rhythms such as respiration and, as we now know, dreaming sleep, imply the presence of endogenously regulated neural oscillations.

4. *Neurons as exclusively excitatory elements versus neurons also as inhibitory elements*. Freud's view of neurons as energy reservoirs probably blinded him to the possibility of inhibitory elements in the nervous system. We return to our analogy of modern neuronal theory as analogous to that of small signal analysis

(negligible amounts of energy) and to Freud's theory as that of large signal analysis or power generation and transmission theory. It is difficult to conceive of a neutralizing force for large signals (high energy), but easier to do so for small signals, for information. One suspects that Freud's strong histological training also may have played a role here; even Cajal never spoke of active inhibitory elements in the nervous system. It is likely that physiologists, accustomed to the obvious possibilities of active reflex inhibition, were more alert to the possibility of inhibitory elements in the CNS, as we have seen in Exner's prescient work.

For whatever reason, Freud did not include inhibitory elements in his neural model. Thus, for altering the pathways of neuronal excitation, he had only the mechanism of *diversion* of energy, or the formation of "side-paths." This diverted energy or excitation remained in the nervous system; it was immutable and persisted unless discharged in motoric activity. In contrast, modern concepts of neuronal function emphasize the possibility of *cancellation* of excitation (i.e., excitation in the modern sense of decreased membrane potential) by inhibition (through the opening of ionic channels that hyperpolarize the membrane). Freud's idea of diversion of excitation (versus the possibility of cancellation) was to have important influences on his later theoretical positions. For example, he conceived of diverted impulses or wishes (i.e., "repressed" wishes) as continually exerting a pressure toward discharge and often emerging in dreams. It is as intriguing to imagine the consequences for Freudian theory if the modern concepts of inhibition had been used as it is difficult to conceive of how modern physiologists would interpret data without them.

The Structure and Dynamics of Freud's Model

We are now ready to combine elements of Freud's model, the neurons, into the structures and paths of energy flow presented in his 1895 model of the nervous system. Figure 1 details this schema and should be consulted while reading this section; tables 2 and 3 summarize the links between Freud's neurobiology and his psychology.

In Freud's model, energy entered from the outside world, encountered a protective barrier or *Reizschutz* that prevented the full force of the energy from entering the first of Freud's systems of neurons, the ϕ or perceptual neurons. From here energy went into the main system of neurons, the ψ or psychic system. There the normal energy flow was toward the motoric system, where energy was dissipated in motoric discharge. Freud believed that primitive organisms functioned on this simple reflex model of stimulus and motoric discharge and that this model formed the basis for all of the more advanced organisms. Both neurons and organisms strived to get rid of energy. In fact, we now know that even in primitive organisms this kind of simple tension reduction or reflex model is inadequate (21).

For more complex organisms there is yet another set of neurons to be considered. Sketched above the other systems are the ω (omega) neurons, or the neurons of consciousness. The dotted lines in figure 1 indicate that these neurons have access to information from the perceptual system and also from the motor system. They have a further important function in Freud's model of sensing the level of psychic energy or *Qn* in the parts of the ψ system to which they have access. High levels of energy or charge are perceived consciously as "unpleasure," while energy discharge is perceived as pleasurable. Thus the higher organism has a strong conscious bias toward the discharge of

FIGURE 1
Freud's Model of the Nervous System

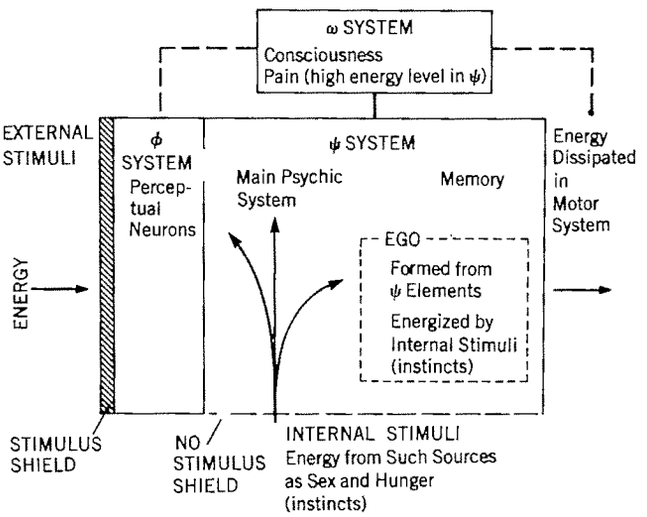

TABLE 2
Isomorphisms Between the Major Structural and Operational Concepts of Freud's Psychological Model and the Neuronal Model of the "Project"

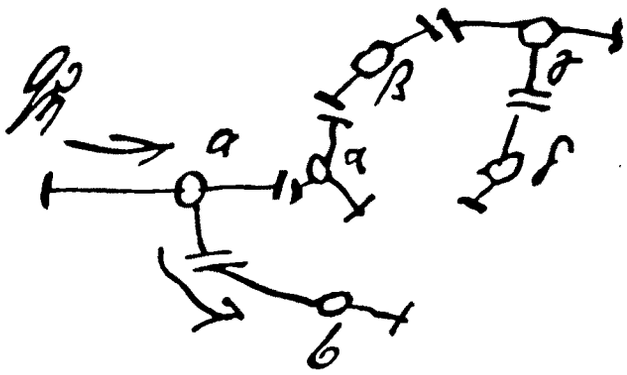
Psychological Model	Physiological Model
Fundamental operating principle of organism is tension reduction, discharge of energy-nirvana principle.	Neurons divest themselves of nervous energy. Omega neurons sense pain as high energy level in the psychic system, pleasure as energy discharge-nirvana principle.
Primary direction of energy flow is from sensory input to motor discharge.	Direction of nervous energy flow is modeled on reflex physiology: sensory neurons → motor neurons.
Critical role of somatic drives for motivation.	Neurons receive *all* nervous energy from *outside* the brain. *Reizschutz* makes somatic input motivationally preeminent.
Lack of ego autonomy, corruptibility of ego processes by impulses.	No autonomous energy source for ego. Ego neurons derive nervous energy from somatic drives.
Chief difficulty of organism is in control of impulses, in discharging internal drives.	"Psi is at the mercy of Q." Immutability of nervous energy; no true inhibition and cancellation of nervous activation is possible. Motoric discharge is sole mode of energy release.

TABLE 3
Isomorphisms Between the Dynamic Processes of Freud's Psychological Model and the Neuronal Model of the "Project"

Psychological Process	Physiological Process
Association as principle of learning.	Reflex physiology: *Bahnungen* (pathways) between simultaneously activated neurons.
Regression in topographic sense.	Regressive direction of nervous energy flow is motor → sensory, the reverse of normal reflex flow.
Primary process thinking, hallucinatory wish fulfillment, psychoanalytic theory of psychosis (and dream imagery).	Overly strong cathexis of mnemic neurons of psychic system → hallucination. Energy is from somatic drive.
The "inhibiting ego" requires energy to divert wishes. Ego is limited in the amount of inhibition possible.	Ego neurons "inhibit" by *diverting* energy through energy requiring side-cathexes. No true inhibition or cancellation of neural activation in the modern sense.
Secondary process thinking.	Ego lessens somatic drive; overcathexis of mnemic neurons through attraction and diversion of the energy via side-cathexis.
Symptom substitution.	Immutability of nervous energy, no inhibitory elements. Blockage of energy discharge → buildup of energy in psychic neurons → tendency to emerge in another form of motoric discharge.

energy, toward what Freud called the "nirvana principle" in the "Project" and in his later works.

The importance of somatic drives—instincts—in Freud's model cannot be overemphasized. Unlike energy from the external world, there was no protective barrier or *Reizschutz* for these internal drives, and thus their full force had access to the entire psychic apparatus. Freud described the consequences in a passage that he underlined for emphasis: "ψ is at the mercy of Q (energy from somatic drives)." Thus Freud's neural model was constructed so that the somatic input of energy was motivationally critical. The multitudinous examples of the importance of the somatic drives (especially sex) in Freud's later writings hardly need emphasis. A plausible argument for why Freud selected the input from somatic drives as critical is that his model of "passive" neurons, which have no independent sources of energy, meant that the brain would of necessity have to receive energy from extracerebral sources and thus either from the external world or from the body. But, as noted in the "Project," the external world is a poor source of lasting motivational power, since painful external energy sources can usually be circumvented simply by moving away; on the other hand, internal sources of excitation, of energy, persist unless the particular drive, such as hunger or sex, is satisfied.



We chose the example used by Freud in the "Project," that of a hungry infant, to illustrate the dynamics of his neural model of the complex organism and the genesis of many familiar psychological concepts in the physiology of the "Project." When an infant becomes hungry, the energy from this somatic drive goes into the ψ system of neurons and the charge or cathexis is then dissipated in the motoric activity of crying. This crying acts as a signal to the mother, who provides a nipple for the infant, and the drive energy ceases with its satisfaction. Freud postulated that the neurons of the ψ system had memory, that the ease of passage across the "contact barriers" (Freud's term) or synapses was altered according to the frequency and amount of *Qn* or psychic energy passing through them. He further used the concepts of reflex physiology transposed to his neurons to postulate that "hot spots" of neuronal activity occurring simultaneously would be linked, that paths of facilitation (*Bahnungen*) would be formed and would remain, because of the memory of ψ neurons. Thus, in this example, the neurons storing the perception of the nipple and those cathected by the somatic energy from hunger would be linked. Freud put the locus of mnemic elements (or memory neurons) near the perceptual end of the psychic apparatus. The next time the infant becomes hungry energy flows from the soma, but because of the *Bahnung* it will now travel toward the mnemic neurons containing the perception of the nipple. These neurons will be very strongly cathected; this overly strong cathexis produces a hallucination rather than a memory.

At this point Freud introduced the term "regression," indicating that the flow of energy is "regressive" toward the perceptual side of the CNS and not the "progressive" and usual path toward motoric discharge. Here also is the origin of the concept of hallucinatory wish fulfillment and the basis of primary process thinking. As will be seen, regressive process also underlies Freud's theory of hallucinations in dreams and further forms the basis for the theory of psychotic hallucinations.

For the infant in the example, mere hallucination of the nipple cannot provide much satisfaction. Freud, not completely in jest, noted that one would have to be schizophrenic to cling to such a hallucination. But the difficulty in terms of the theory is how this neural modeler of the 1890s altered the course of energy away from the overcathected mnemic elements responsible for the unsatisfactory hallucination without having any inhibitory elements in his model of the nervous system.

Freud, in fact, was driven to postulate another principle of neuronal energy flow, one for which there was not (and is not) any experimental evidence. Figure 2 presents Freud's sketch of the normal direction of energy flow in a set of neurons. Freud attempted to deal with this dilemma by positing that a charge or cathexis in a postsynaptic neuron will attract *Qn* to it and thus can divert nervous energy from its normal path. Freud spoke of this diversion of energy as "inhibition," but his concept was distinctly different from the modern concept of inhibition and rested on inaccurate assumptions about neuronal functioning. The chief con-

FIGURE 2
Freud's Sketch of Neurons and the Flow of Neural Energy*

*This sketch illustrates Freud's concept of diversion of neural energy through a "side-cathexis." The normal flow of energy (arrow labeled *Qn* in Freud's script) is to neuron b; Freud postulated that a side-cathexis of neuron alpha would attract *Qn* and divert the flow from neuron b. Freud believed this postsynaptic attraction of energy or side-cathexis (for which there is no experimental support) to be the neuronal mechanism underlying repression.

sequence of Freud's concept of side-cathexis for his theory of the operation of the nervous system is that nervous energy can only be diverted, not cancelled, and it further increased the vulnerability of his model nervous system to an overload of energy.

In the example of the hungry infant, Freud said that the flow of energy is diverted away from the mnemic neurons by the use of such a side-cathexis. The lesser intensity of the cathexis of the mnemic elements produces a memory, not a hallucination, and the infant is able to compare this mnemic image with its perception—an example of *secondary process thinking*.

Freud believed that the "inhibitory" side-cathexes of this nature were made by a specialized set of neurons of the ψ system; he called this subsystem the "ego." This familiar psychological construct and even the psychoanalytically familiar phrase, "the inhibiting ego," had its origin at this point in the "Project."

A final comment on the dynamics of the neuronal model of the "Project" concerns the origin of the terms "repression" and "primary defense." Freud thought that perceptions of objects that had proved painful in the past were associated with a great deal of painful affect (i.e., excessive energy) because the perceptions were associatively linked to "key neurons" whose secretions (i.e., hormone-like activity) stimulated endogenous somatic sources of *Qn* and thus unpleasure. In fact, figure 2 represents such a neuron (labeled "b"), the "inhibition" of the course of energy toward the key neuron b is called primary defense, and the exact same mechanism of diversion of neuronal energy flow through ego side-cathexes is termed "repression" in the discussion of hysteria in the "Project."

Thus a recognizably Freudian theoretical system with its corpus of familiar clinical concepts is now evident in the *neural* model (see outline in tables 2 and 3). In fact, the entire psychic model and almost the entire theoretical structure of "The Interpretation of Dreams" and, indeed, much of Freud's later work is now comprehensible, since it is directly derived from the neurophysiological brain model of the "Project."

Overview of Freud's "Project"

This overview of Freud's "Project" will allow a discussion of the principal characteristics and difficulties of an organism constructed according to Freud's 80-year-old specifications. The most salient difficulty and unreality in Freud's model is an energy economy based on a demonstrably false conception of neurons and synapses. Using this false conception as a basis, Freud modeled an organism whose primary principle and goal is tension reduction, whose conscious elements register unpleasure when the energy level is too great, and who is subject to unshielded bombardment from internal drive energies—all three dubious assumptions.

Furthermore, the organizing, executive neurons (the ego) themselves do not have the possibility of direct inhibition of drives—as would be possible if this were a "small signal" instead of a "large signal nervous system" and if Freud had conceived of inhibitory elements. Energy can only be diverted or stored, but it retains its power, forever a threat to the organism's comfort, even though restrained for the moment.

We think it fair to say that one would expect the organism of the "Project" to be dominated by drives and to be in constant danger of being overwhelmed by them. It is not too great a caricature to call the "Project" a "cat on a hot tin roof" model, with the persistent internal drives generating blasts of energy that keep the ego and conscious system in frenzied movement.

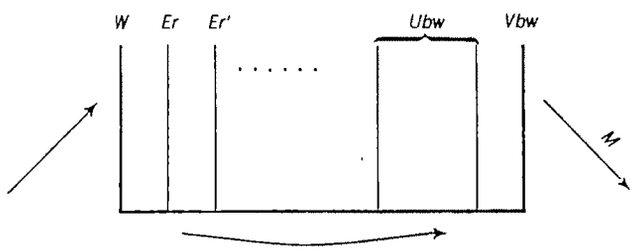
It should be further noted that, since energy from drives can be diverted but not cancelled or discharged internally, suppression of one form of motoric dissipation inevitably leads to an internal energy buildup with the likelihood of flow into another motoric act. This is the primitive analogue of the doctrine of *symptom substitution* and is directly based on Freud's mistaken concepts of the immutability of nervous energy or excitation and the absence of inhibitory nervous elements.

The absence of self-generated activity and energy postulated by Freud's model for neuronal systems leads directly to the notion of lack of autonomy for psychological systems. The source of the postulate of ego dependence on drive energy originates in the physiology of the "Project," and one legacy of this inaccurate physiological model was the necessity of a long, difficult struggle by psychoanalytic ego psychologists to convince conservative analytic theorists that the ego should be regarded as autonomous (22, especially chapter 9).

It must be emphasized that there are also positive features for later psychological theory in the dynamism of Freud's CNS model. It is fluid in its postulates of facilitation and already embodies a rather specific, although ancient, learning theory: psychological asso-

ciation through temporal contiguity, represented neurally by facilitation between simultaneously occurring "hot spots" of neural activity. There is, further, the inclusion of the specific postulates of classical conditioning and a neuronal model of the mechanisms. This neuronal theory of learning provides a possible bridge to the concepts of what is today called learning theory. This link has not been sufficiently recognized and thus not used; even one of the classical works on conditioning and learning (23) fails to point out the common parenthood with psychoanalysis.

A few comments should be made about Freud's intellectual style and strategy as seen in the "Project" and in his letters about the "Project" (17). Because there was no final draft or publication of the "Project," the alternative and tentative approaches of Freud remain. They testify to his devotion to modeling and to theory and to his enchantment with logical coherence. He was elated when his model appeared to work and despaired when it ran into difficulty. He abandoned further formal work on the "Project" when, even after several revisions, he could not get his notion of the omega system (or consciousness system) to mesh satisfactorily with the other elements. However, what Freud kept was this notion of the basic principles of how the brain and mind work.



Amacher (24), in commenting recently on the extent of Freud's devotion to theory, emphasized that Freud's first impulse in cases of difficulty with empirical data was always to "save the theory," whether it was his theory of dreams or his theory of sexuality. This characteristic of Freud makes it understandable why the theories of the "Project" are of such critical importance for an understanding of Freud's later work. Examination of "The Interpretation of Dreams," the work Freud valued most highly, reveals many specific examples of theoretical similarities, its isomorphism with the "Project."

Freud's Dream Model

The seventh and most theoretical chapter of "The Interpretation of Dreams" (1, 2) outlines what Freud described as a psychological model of the psychic apparatus (see figure 3). However, it is in fact virtually the same model as that set out for the brain in the "Project" and should be compared with figure 2. Table 4 also summarizes some of the links between dream processes and the neuronal mechanisms of the "Project."

This "psychological model" of figure 3 has the same perceptual system as the "Project," although the abbreviation ϕ is not used. As in the "Project," excitation flows into a familiar second system. The psychic system of "The Interpretation of Dreams" includes three subsystems: mnemic elements; the unconscious, to be thought of as those psychic elements in contact with instincts and not open to the conscious system (the consciousness elements are not included in Freud's sketch); and, finally, the preconscious, composed of those psychic elements in close apposition to consciousness.

FIGURE 3
Freud's Model of the Psyche*

*This model appears in the seventh chapter of "The Interpretation of Dreams." W is the German abbreviation for the perceptual system. The constituent elements of the main or psychic system (not labeled as such in the original figure) are as follows: Er, memory; Ubw, unconscious; and Vbw, preconscious. M indicates the motoric system. The arrows indicate the normal direction of energy flow. Although Freud did not include as much detail in this drawing, the full model as outlined in his text is virtually identical to the brain model of the "Project" that is sketched in figure 1.

TABLE 4
Isomorphisms Between Freud's Dream Theory and the Neuronal Model of the "Project"

Dream Process	Neuronal Process
Sleep paralysis.	Withdrawal of ego cathexis from motor apparatus.
"Power supply" of dream is a wish, derived from somatic drive.	All neuronal energy comes from outside the brain; somatic energy has no stimulus barrier.
Dream process is a reaction to events *outside* the CNS, i.e., the combination of day residue with instinctual wish.	No autochthonous energy source or regulatory power for brain neurons. They are passive recipients of energy.
Regression of psychic energy after censor blocks access to consciousness.	Flow of nervous energy is toward perceptual end of apparatus.
Dream work, dream hallucinations. Dream guards sleep by disguising wish.	Overcathexis of mnemic neurons near sensory side of apparatus → hallucinations. *Bahnungen* (pathways) between wish and mnemic elements related to wish furnish the disguised representation of the wish.

Freud did not include the "psychic censor" in his sketch, but his text description of psychic topography placed its elements between the unconscious and preconscious; the psychic censor acts to screen and block wishes unacceptable to consciousness. The psychic censor is conceptually derived from the set of neurons in the "Project" that were responsible for repression. This subject will be discussed in more detail in a later section of this paper.

The outline of Freud's dream theory is straightforward. The ego wishes to sleep (the causal basis for this wish is not clear); it withdraws its cathexes from the motor system, resulting in sleep paralysis. The dream process begins when something in the day's ex-

perience stirs up a repressed wish in the unconscious. They pair forces and seek to move in the usual direction of flow in Freud's model (see arrow in figure 3) toward the preconscious system. Entry of the undisguised wish is blocked by the censor, and there is a regressive movement of the "currents of excitation" toward the mnemic elements of the psyche, which, as in the model of the "Project," are close to the perceptual side of the psychic apparatus. There the "dream's work" of condensation, displacement, and symbol formation takes place with a disguise of the wish by the imagery of those mnemic elements with the strongest associative links to the wish. The disguised wish thus becomes acceptable to the censor and is passed into consciousness. Freud believed that the dream functioned as a guardian of sleep by preventing the intrusion of undisguised and unacceptable wishes into the conscious system, with subsequent arousal.

As for dream phenomena, Freud concentrated on the symbolic grammar employed and focused his interpretive powers on unraveling the psychic meaning of symbols and the thematic material of dreams. He paid relatively little attention in "The Interpretation of Dreams" to certain formal sensory, temporal, and intensity attributes of the dream, but he did note that the psychic or subjective intensity of a dream image reflects the underlying intensity of the wish (its charge) and the number of excitations condensed into a single symbol or wish. He suggested that the frequent subjective sense in dreams of little or no movement was related to the sensing of sleep paralysis. Most importantly, Freud asserted that the forgetting of dreams is "inexplicable unless the power of the psychic censorship is taken into account," i.e., we forget our dreams because of psychic repression. Freud saw in the forgetting of dreams the prime support for his "wish fulfillment-disguise" theory of dream generation.

Thus Freud's psychic model was quite simply derived from the physiological constructs of the "Project." The psychic and neural agencies are virtually the same, their organizational sequence and function are the same, the direction of flow of energy is the same, and the reflex model is retained. The psychic "elements" share the properties of the "Project's" "neurons" in that "excitation" is "transmitted" according to "conductive resistance." "Association" results from "facilitating paths." Freud even talked about "currents of excitation." In short, virtually the entire neural theory of the "Project" was retained despite Freud's assertion of creating a psychological model.

MODERN PHYSIOLOGY AND REVISIONS IN FREUD'S THEORY

Implications for Psychoanalytic Dream Theory

We have discussed in detail how Freud's theory, his model of the psyche and of dream processes, is based on his neuronal model of the "Project." We will now briefly address the revisions in Freud's theory that are necessitated by the 80 years of neurophysiological research since the "Project." Our related article (3) will present the results of modern sleep physiology on which these conclusions rest.

Freud believed that the dreaming sleep state (D) and dreaming were initiated and powered by the combination of the day residue (certain memories from the day) with the energy contained in a repressed, unconscious wish (see table 4, item 3). It can now be categorically stated that there is *no* experimental support whatsoever for Freud's theory of D-state generation. Instead, modern investigations point to autochthonous, periodic, and motivationally neutral activation of pontine generator neurons as the cause of the D state (25–27).

The rhythmic state-generation property of these pontine brain stem cells points to other fundamental difficulties with Freud's CNS model, since he nowhere postulated autochthonously active and autochthonously regulated neural systems or their counterpart. The simple conclusion is that Freud's theory regarding the lack of autochthonous activity and the lack of regulation and endogenous energy for the brain must be abandoned. This is not to suggest that day residue material or motivationally important themes do not enter into dream content; they may do so, but neither is a causal factor in the dream process.

There is no need to postulate the repression of *Qn* (or of wishes, if one prefers this label for neural energy) to provide generative power for the dream state. The energy is already *in* the CNS. For D generation there is also no need to postulate the existence of the unconscious as the psychic subsystem or collection of neurons necessary for the storage of the energy of repressed wishes, and there is nothing to suggest that the concept of repression is in any way germane to controlling the activity of the pontine cells responsible for D generation. Intrapontine, autochthonously proceeding, and active cellular mechanisms are all that is required. Further, the concept of regression in the sense of a reversed flow of neural energy is not needed or even correct. The pontine executive cells conduct in the same direction that they do during waking; they just become some 40-fold more active in the D state.

There is also serious difficulty with Freud's theory that the primary motivating force for the dream language and dream plot is disguise of a repressed wish. The driving force for D sleep is a biologically determined and *motivationally neutral* activation of cells in the pons, not a repressed wish. There is no evidence whatsoever that these cellular mechanisms of generation are in any way driven by hunger, sex, or any other instinct or by repressed wishes for consummation of instinctual drives. The *primary motive* for the dream language and dream process cannot be disguise if the prime force of dreams is not an instinct or repressed "wish" in need of disguise. Our related article (3) will discuss alternative mechanisms for some aspects of dream phenomenology.

Implications for Psychoanalytic Theory in General

It is beyond the scope of this paper to present a detailed discussion of the implications of the inaccuracies in Freud's neural model for general psychoanalytic theory, as opposed to dream theory. It does appear worthwhile, however, to use what had been discussed as a basis for looking at responses to the problems in Freud's theory and the merits of various strategies for dealing with them.

There have been two major reactions to the inaccuracies in Freud's model. The first of these is seen largely in clinical settings. Those engaged in clinical work may acknowledge the theoretical difficulties with many of Freud's concepts but continue to use them in their conceptualizations of patients simply because there is no equally comprehensive alternative theory. Thus at the clinical level the use of concepts such as impulse breakthrough, symptom substitution, object cathexis, and instinctual energy remains common, even though the user may have some intellectual misgivings.

The second kind of response is to attempt to deal with the problems associated with a certain specified and apparently delimited portion of Freud's model, usually to what is termed "energetics" or the "energy economy." One then suggests the substitution of some more appropriate concept, i.e., one more in harmony with modern neurobiology. The often unappreciated difficulty is that what is labeled as a simple problem in "economics" is, in fact, a problem with fundamental postulates and thus the *entirety* of Freud's model. Freud's model, like complicated models in general, cannot be easily revised by the simple substitution of a single concept. The alteration of one of the fundamental premises has profound effects on the model as a whole, and it is further impossible to segregate aspects of Freud's model into neat, easily differentiable sections that can be dealt with in isolation.

An examination of the concept of repression illustrates some of the complexity of revision. This concept originated in the neuronal model of the "Project." Freud noted that hysterical repression is based on the mechanisms of diversion of nervous energy (*Qn*). "Thus there is a defensive process emanating from the cathected ego which results in hysterical repression . . ." (14, p. 351). The basic mechanisms and concepts are the same as those we have discussed for primary defense: the use of side-cathexes, release of unpleasure by key neurons, and quantitative aspects of the energy economy. "The stronger the release of unpleasure the harder was the task for the ego, which, with its side cathexes, can after all provide a counterweight to the *Qn* up to a certain limit . . ." (14, p. 358).

Can this concept of the mechanisms of repression originating in the mechanisms of the "Project" be easily revised by a simple updating of the "neuronal energetics"? One must conclude that it cannot, since it rests on several incorrect assumptions of Freud's model: not only on his erroneous theory of energetics, but also on the absence of inhibitory elements, the absence of the possibility of cancellation of excitation through inhibition, and a mistaken notion of synaptic transmission (side-cathexes do not "attract" and bind neuronal energy). It is apparent that to update the concept of repression one would have to alter several assumptions of the model. Thus this example of a clinically central concept supports the position that one cannot revise by, for example, simple substitution of "neuronal discharge" wherever Freud talks about *Qn* or nervous energy.

Still another reaction to the inaccuracies in Freud's model has been to ignore the erroneous neurobiology and attempt to create more abstract and purely psychological models, such as Breger and associates (28, 29) sought to do for dream theory. In their discussion of the "Project," Pribram and Gill treated Freud's discussion of neuronal physiology and mechanisms as a metaphor for psychological processes, "something that should . . . become part of the heritage of academic cognitive psychology" (20, p. 11). We believe that this approach runs into serious difficulty because such abstract models are even more difficult to specify in detail than the original and thus even more difficult to test (see a more complete discussion of this topic in reference 10).

In contrast to these reactions, we take a critical historical approach that attempts to acknowledge, identify, and correct the erroneous neurobiological assumptions. We submit that these assumptions cannot be denied, but they *do* critically determine psychoanalytic psychology, and that their adequate revision represents an important source of strength for dream psychology. The succeeding paper on the activation-synthesis model of dream phenomena will continue in the tradition of seeking mind-body isomorphisms but will recognize both the value and necessity of limited approaches consonant with the current level of development of neurobiology.

SUMMARY AND CONCLUSIONS

Freud built his model of the mind and his hypotheses about dreaming, which appear in "The Interpretation of Dreams," directly on the structure of his neurobiological model of the brain as developed in his "Project for a Scientific Psychology." Freud developed the theory of both models during the same year, and both are closely related to his work as a student and research worker in neurobiology and to the theories current in the neurobiology of the 1890s. The neurobiological foundations of "The Interpretation of Dreams" and the extent of the isomorphism between Freud's model of the brain and of the mind are generally unrecognized, as is the need to modify those portions of Freud's dream theory and general psychology that are based on inaccurate neurobiology.

Because he developed the theory for both models in 1895, Freud could not have known of modern evidence

that neurons are elements of a signaling network, that neurons have their own metabolic sources of energy and influence one another by the transmission of *small* amounts of energy. Freud conceived of neurons as if they were passive elements in a power transmission network; he believed that all neural energy was entirely derived from outside the brain, chiefly from somatic sources, from instincts. Neurons acted as passive conduits and storage vessels for this energy. Freud did not conceive of the possibility of inhibitory neurons that could *cancel* excitatory signals; in his model energy could only be *diverted* or repressed. Motoric discharge was the sole method of energy dissipation. This neural model was one that left the psychic system, in Freud's words, "at the mercy" of somatic drives. The "Project" and its neural model are of great importance because most of Freud's theoretical concepts were developed there, including those of the ego, nirvana principle, primary and secondary process, hallucinatory wish fulfillment, the inhibiting ego, repression, displacement, and regression.

Examination of Freud's theory of dreams and D-sleep generation (for which Freud assumed the same mechanisms) shows the problems associated with theory developed from the inaccurate neurobiological assumptions of the "Project." In accordance with the assumption that energy comes only from outside the brain, Freud postulated that the "power" for generation of D sleep arises from a repressed instinctual wish, from diverted instinctual energy that becomes linked to a recent memory (day residue). Freud's model assumed a nervous system that reacted to external and somatic stimuli, not one with independently active neural regulation.

Modern investigations have established that the generators for D sleep are motivationally neutral and consist of actively, autochthonously regulated oscillations of neural activity in the pontine brain stem, in contrast to Freud's theory of passive neural elements. Freud believed that the characteristic phenomenology of dreams was the product of an attempt to disguise the instinctually based wish that generated the dream. Since D-sleep generation results from the motivationally neutral activation of pontine executive cells, disguise cannot be the primary motive for the characteristic dream phenomena. Our related article (3) will build on modern knowledge of sleep physiology in proposing an activation-synthesis model of some elements of the dream experience.

Cost, Utilization, and Utilization Review of Mental Health Services in a Prepaid Group Practice Plan

BY SIDNEY S. GOLDENSOHN, M.D.

The author describes the utilization review process, utilization patterns, and service cost of the Mental Health Service of the Health Insurance Plan of Greater New York (HIP). He finds that a mental health care delivery system within a health maintenance organization offers the advantages of sophisticated utilization review procedures, reduced cost per mental health incident, and a low utilization rate and low cost for psychiatric hospitalization. However, the HMO's return-to-function treatment goals may be too limited for the minority of patients who would benefit only from long-term intensive treatment. He recommends that cost accounting be based on cost per illness rather than cost per service.

IN RECENT YEARS the public, legislators, and mental health professionals have shown a growing concern that mental health care be of high quality and be provided at reasonable cost. A critical challenge is thus posed: how do we improve the effectiveness of mental health care and at the same time control or reduce its cost? The delivery of comprehensive mental health care as part of a health maintenance organization (HMO) has several attractive accountability features: 1) reasonable cost per illness for outpatient mental health care due to its "return-to-function" treatment goals (these goals are compatible with an enrolled population that is largely lower-middle to middle class or blue collar); 2) low cost for inpatient mental health care due to a low rate of hospital utilization; and 3) availability of utilization review mechanisms to help achieve quality of care. A regrettably limiting feature in the search for quality care in the HMO system is that its return-to-function therapeutic goals may not be optimal for the nearly 1 in 4 psychiatric patients who come from well-educated and middle- to upper-middle-class populations.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Goldensohn is Director, Mental Health Service, Health Insurance Plan of Greater New York (HIP), 625 Madison Ave., New York, N.Y. 10022.

The author wishes to thank Dr. Donald N. Logsdon, Medical Director of HIP, for his ideas and stimuli toward increased accountability, and Dr. Raymond Fink, Director, Research and Statistics of HIP, for his collaboration on the analysis of the HIP statistical data.

In this paper I will present my experience with accountability based on my work with the Mental Health Service of the Health Insurance Plan of Greater New York (HIP). I will describe this program's utilization review process, utilization patterns, and cost of services.

Relevant aspects of HIP's Mental Health Service will be reviewed briefly; more complete descriptions have been reported elsewhere (1–4). Mental health services are available to HIP subscribers on the basis of a rider to the prepaid health insurance plan. Approximately 180,000 enrollees have purchased the psychiatric rider. The premium (for the time period covered in this paper, January–December 1975) was $10.80 per person per year, $21.60 per couple, or $32.40 for a family of 3 or more. When adjusted for large families, the cost came to $8.76 per person. Psychiatric coverage is provided without coinsurance or deductible features. Premiums are paid to the plan and are used entirely for prenegotiated mental health services. This financing mechanism contrasts with fee-for-service insurance, in which a subscriber is indemnified for expenses incurred in obtaining mental health services in the open market.

The Mental Health Service of HIP offers a broad spectrum of mental health services. The basic therapeutic orientation is psychodynamic; the goal of treatment is to return the patient to a functioning level as promptly as possible. The usual in-hospital treatment modalities are provided for the maximum period of time covered by the patient's Blue Cross contract. Psychotropic drugs are supplied without additional cost to the patient both in and out of the hospital. A ratio of 12 full-time professionals per 60,000 enrollees is necessary to provide mental health services in HIP's three regional centers.

UTILIZATION REVIEW

Utilization review is an important tool in achieving both quality assurance and cost containment. A procedure designed to assure that all services given are necessary, it is used to analyze and identify factors that may contribute to unnecessary or ineffective utilization; potentially it might lead to the development of more precise standards of diagnosis and treatment through statistical analyses (5). Utilization review includes review of individual cases as well as review of

program-wide patterns of utilization. Program-wide review is based on the assumption that an important dimension of quality care is the degree to which mental health services are reaching populations at risk.

Utilization Review of Individual Cases

All cases are reviewed after a 6-month period of relatively uninterrupted weekly therapy. This review can uncover stalemated, nonproductive patient-therapist relationships. When problem cases are routinely discussed, the continuation of treatment without evidence of progress is less likely to occur unchallenged (6). In keeping with our treatment goals, one question that is always asked in the case review is, Has the patient or family already returned to a functioning level of performance? Case review may help the therapist terminate treatment when these goals have been achieved; help the therapist terminate treatment because no further change (within our system) can be anticipated; help the therapist overcome a clinical impasse; and, finally, provide agreement with and support for the therapist's current management of treatment.

Program-Wide Utilization Review

In 1975 the Mental Health Service's overall annual utilization rate for new psychiatric consultations was 11.0 per 1,000 population; 18.3 for the Medicaid population; 11.7 for both state and federal employees; and 5.8 for Medicare enrollees. The number of therapeutic sessions provided to each subscriber group per 1,000 population followed a similar pattern (see table 1). Data are also available on utilization in each of the three regional centers.

Review of utilization data of the entire Mental Health Service has helped to improve care by indicating needed program modifications. Two examples will illustrate the usefulness of program-wide utilization review. Two years ago one of the three regional centers was found to be highly successful in reaching its underserved poor population. It was then relatively simple to examine and determine what this center was doing that the other two centers were not. Within an 18-month period, all three centers were reaching their Medicaid enrollees at about the same high utilization level. A second example was the discovery that one center was reaching less than half the number of elderly patients that the other two centers were reaching. Again, examination of the operation led to the discovery of what should prove to be corrective measures.

In both these instances the single most important factor necessary to adequately reach underserved populations proved to be a sufficient number of staff. Patients (particularly the poor and aged) who must wait for services tend to turn away, and so do the sources that referred them. Another factor of importance for serving minority groups is the presence of a multilingual and interracial staff. The aged and poor also need a staff that is able to move out into the medical group centers where these subscribers receive their medical care.

Program-wide utilization review can also predict future patterns of service with fairly good accuracy; some of these predictions may be helpful administratively. For example, Medicare utilization data reveal that only approximately 18% of aged patients attended more than 15 treatment sessions in a year, that only 3% attended more than 40 sessions, and that 50% were seen for 5 or fewer visits per year. The adult state employee group offers the greatest contrast to Medicare enrollees: 33% of these patients attended more than 15 sessions and another 33% were seen for only 5 or fewer visits per year. (Patterns of utilization by major subscriber groups are presented in table 2.) The stability of these patterns helps in planning staff size and staff deployment. The information is also useful in supervising clinical personnel.

Utilization by Medicare

Although the Social Security Administration's policy on mental health coverage is beyond the scope of this paper, I would like to make a few comments on the subject. The over-65 subscriber (the Medicare subscriber) has the lowest utilization rate of mental health services nationally (7). The consultation rate for HIP's Medicare population was 5.8 per 1,000 in 1975. This compares with a consultation rate of 14.3 per 1,000 for those below the age of 65. The rate of services that the Medicare population receives was also low: 83 per 1,000 population, compared with 221 services per 1,000 for the under-65 population (see table 1). The low utilization of mental health services by the aged contrasts strikingly with their high utilization of other medical services. These figures make it hard to understand why the federal government discriminates against psychiatric treatment benefits under Social Security. The present limit of coverage for outpatient treatment in the open market is a maximum payment of $250 or 50% of reasonable charges, whichever is less, after a $50 deductible. A case for coverage equal to that for medical illness is clearly indicated.

COST

Cost per Illness

The cost per session at this HMO is not significantly different from that in private practice. At present it is about $50 per session. A natural question follows: Is there any cost advantage to mental health care provided by an HMO delivery system? I believe that the answer is yes but that the costs must be computed on a cost per illness per year basis rather than on a cost per service basis. There is a growing tendency in the mental health field to report costs on a per illness basis (8–12).

Obviously, a reduction in the number or length of sessions required to help a patient will reduce the cost proportionately. Spaced monthly visits and half-hour

TABLE 1
Utilization Data for HIP's Mental Health Service (MHS) for 1975

Item	Medicare Subscribers (N=70,242)	Medicaid Subscribers (N=40,168)	Federal Employees (N=37,761)	State Employees (N=25,879)	Total* (N=177,096)
Number of treatment sessions to MHS rider patients in 1975	5,848	9,931	8,039	4,926	29,512
Treatment session utilization rate per 1,000 1975 rider population	83	247	213	190	167

More than 40**	27	3.0	47	2.7	45	3.9	20	3.2	135	2.9

*Totals are slightly higher than the indicated breakdown due to utilization by small subscriber groups (not shown).
**These figures indicate that 2.9% of all patients received 13.1% of all services (N=49,884); for the Medicare subscribers, 3% of the patients received 15.2% of all services (N=9,005); for the Medicaid subscribers, 2.7% received 11.3% of all services (N=16,335); for the federal employees, 3.9% received 15.6% of all services (N=14,200); and for the state employees, 3.2% received 11.7% of all services (N=8,558).

sessions have been found to be highly effective for selected patients. Even dynamic insight therapy can be productive with visits at monthly intervals.

Socioeconomic Class and Goals of Treatment

The middle-class and blue-collar subscribers who make up the majority of this HMO population find the return-to-function treatment goals of our plan basically compatible with their own treatment goals. The average number of services per patient per year in the Mental Health Service has ranged between a low of 14.5 in one year to a high of 16.3 in another (15.2 in 1975). Using $50 as the average cost per session, the average cost per illness or mental health incident at HIP comes to $760 per year. This includes outpatient and inpatient mental health services but not the cost of hospitalization.

In private psychiatric practice, which, as a rule, in-

volves middle- and upper-middle-class patients, treatment goals often involve characterological change, self-realization, or achievement of a patient's highest possible potential; these goals require lengthy treatment at high cost. A recent survey of private psychiatric office practice conducted by the Joint Information Service of APA and the National Association for Mental Health (13) reported an average of 38 sessions per patient per year when psychoanalytic patients were excluded and 46 visits per patient per year when they were included. For psychoanalytic patients only, the number of visits jumped to 138 per year. Using $40 as the average private fee, the cost per mental health incident for the average private patient, excluding psychoanalysis, came to $1,520 per year. When psychoanalysis was added, the cost per incident per year rose to $1,840; the cost per average patient in psychoanalysis was about $5,000 per year.

With return-to-function goals, the cost per illness will predictably be modest; with goals that include long-term therapy, the cost per illness must rise. Nevertheless, long-term therapy appears to be insurable (7, 14) because only a small number of recipients utilize these services.[1] In comparison with the cost for physical illnesses, the cost of mental health services is relatively stable, predictable, and reasonable. The late Dr. Louis Reed's report on insurance data (15) supports the belief that, providing the insured base is national, probably less than $15 per person per year could cover both inpatient and outpatient psychotherapy, including long-term psychoanalytic treatment. However, elective treatment, i.e., treatment for self-actualization or training purposes, would not be covered.

A HIP pilot study concluded that optimum coverage in an HMO would provide intensive-reintegrative therapy for the approximately 3% of the patient population who would not significantly improve otherwise, as well as for the estimated one in 10 who could electively benefit by it. For most of the patient population (approximately 87%), return-to-function goals are more appropriate, more practical, and more therapeutically valid. Theoretically, there is no reason why long-term therapy could not be included in an HMO plan if the premium were increased to cover the utilization of an upper-middle-class or mixed population.

Indirect Expenses

As would be expected in view of their basic philosophy, HMOs are concerned with preventive psychiatry. They operate on the premise that reduction of psychopathology through preventive measures and comprehensive mental health care reduces the requirement for other medical services and therefore may indirectly save the organization money (16, 17).

Approximately 30% of the therapist's time in the HMO is spent in personal and/or telephone contacts with outside agencies, school personnel, and relatives of patients; in consultation with referring physicians; in teaching seminars for HIP medical group physicians; in subscriber education programs; and in in-service education. In comparison, it is estimated that 5%–10% of the private practitioner's professional time is expended on preventive measures and what can be called "comprehensive aspects" of mental health care. Since these indirect services are absorbed in determining the cost per visit, HMO and private practice cost per visit data are not truly comparable.

Interdisciplinary Staff

Another consideration in cost containment for an HMO is its use of the lesser paid disciplines as providers of psychotherapy. Approximately 30% of the mental health services in our program are provided by psychiatrists, 30% by psychologists, and 40% by psychiatric social workers. A 1975 report from the Group for the Advancement of Psychiatry (4) pointed out that the HMO system tends to attract highly skilled nonpsychiatrist professionals because there is a greater supply of available manpower in nonphysician categories and because salaries for them are more competitive in HMOs.

Community Resources

Our Mental Health Service uses available community resources for services that are not covered, such as vocational rehabilitation services, day hospital centers, state hospitals for chronic hospitalization, and visiting nurse services for home care. This permits broad mental health coverage without increasing the premium to the subscriber; however, for national health insurance purposes, the cost for these services should be included in order to arrive at a total cost per illness.

HIP's Mental Health Service maintains most of its chronic psychotic patients within the community and outside the state hospitals. It is fiscally feasible to have these patients seen by a physician indefinitely as long as monthly visits, with or without medication, prove to be sufficiently supportive for their maintenance.

Hospital Utilization

Still another very important fiscal concern is the high cost of psychiatric hospitalization. The utilization of psychiatric hospitalization is characteristically low in prepaid group practice programs. During 1975, only .7 per 1,000 of the HIP mental health rider population were hospitalized for psychiatric care. This represented 6.4% of the year's Mental Health Service patient population (see table 1). Non-HMO hospitalization rates are more than 4 times higher for comparable socioeconomic groups (18). The patient's average length

[1]Blue Cross and Blue Shield data for Washington, D.C., showed that approximately 13% of the psychiatric patients used 64% of the dollar expenditures (7). Our data at HIP showed that 10% used 34% of the expenditures. However, the Joint Information Service survey data (13) are disquieting in that if they are projected into national health insurance coverage, the 86% of families in the United States whose earnings are under $20,000 a year would pay the greatest share of the cost for services largely rendered to individuals in families whose incomes are over $20,000 a year.

of stay, once he or she is hospitalized, is higher for the HMO than for comparable groups, 15.8 days compared with 12.1 days (18). The markedly lower number of patients hospitalized, however, makes for a critical cost saving.

The low rate of psychiatric hospitalization in the HMO is due to two factors: the early, continuing, and ever-ready (24-hour) availability of outpatient coverage; and the absence of the kind of financial incentive for hospitalization that exists in indemnity plans that offer payment for psychiatric patients only if they are hospitalized.

MEDICAL AUDIT

The best means of assuring quality control is through an assessment of the treatment process and outcome. At HIP we have started to collect data on outcome. We hope that this research will provide information on the interrelationship of the patient's chief dysfunctional behavior or symptoms and the following factors: the therapist's predicted treatment plan, subsequent changes in the treatment plan, the duration of treatment, the psychopharmacologicals prescribed, and treatment progress and outcome.

CONCLUSIONS

The inherent danger in concentrating on accountability is that we may lose sight of the patient. We must ask ourselves (19), Are the clinical needs of the patient, rather than the need to contain costs, the primary focus? The critical challenge remains one of maintaining or improving the quality of mental health care for the patient while at the same time controlling or reducing its cost. We expect that this problem will be met creatively by the development of new and more effective modalities and techniques of psychotherapy, by the discovery of illness-specific treatment regimens, and by improved and more economical systems of mental health delivery.

Cost accounting in mental health care should be based on cost per illness rather than cost per service in order to better evaluate the financial effectiveness of different delivery systems. At present, however, such comparisons are at best complex and of limited validity (12).

An HMO delivery system for mental health care offers certain advantages in the area of accountability: the use of sophisticated utilization review procedures, reduced cost per mental health incident, and a low utilization rate and low cost for psychiatric hospitalization. However, an important positive factor for cost containment, namely, the HMO's return-to-function treatment goals, also proves to be a potential handicap to providing quality care. These goals are perceived by some of the better educated and upper-middle-class patients as too limited. For some patients from all socioeconomic classes (estimated variously between 3% and 25% of psychiatric patients), these goals may prohibit the delivery of an essential treatment modality. However, with a modest increase in premium, the more costly long-term therapeutic modalities can be covered without losing many of the advantages of prepaid group practice.

Cyclothymic Disorder: Validating Criteria for Inclusion in the Bipolar Affective Group

BY HAGOP S. AKISKAL, M.D., ARMEN H. DJENDEREDJIAN, M.D., RENATE H. ROSENTHAL, PH.D., AND MUNIR K. KHANI, M.D.

The authors identified 46 cyclothymic probands from a random pool of 500 psychiatric outpatients and prospectively followed them over a 2–3-year period. They used 50 bipolar patients with a definite history of mania and 50 patients with personality disorders as control groups. Although 66% of the cyclothymic outpatients had previously received the diagnosis of hysteria or sociopathy, their pedigrees were similar to those seen in classical bipolar manic-depressive illness; furthermore, 44% of the cyclothymic group experienced brief hypomanic episodes while taking tricyclic drugs, and 35% developed full-blown hypomanic, manic, or depressive episodes during drug-free follow-up. The authors conclude that these findings provide evidence for a cyclothymic-bipolar spectrum.

> There are certain temperaments which may be regarded as *rudiments of manic-depressive insanity*. They may throughout the whole of life exist as peculiar forms of psychic personality without further development; but they may also become the point of departure for a morbid process which develops under peculiar conditions and runs its course in isolated attacks.
>
> —Kraepelin (1, p. 118)

THE TERM "CYCLOTHYMIA" was coined 100 years ago by Kahlbaum (2) as a unifying clinical concept for what was then known as "circular insanity." Although some European authors such as Kurt Schneider (3) have referred to the entire domain of manic-depressive disorders as cyclothymia, the Anglo-American literature (4–6), following Kraepelin (1) and Kreschmer (7), generally restricts cyclothymia or cycloid personality to the subaffective personality conditions seen in the biological relatives of manic-depressive patients. Furthermore, other workers have reported that cyclothymic and related temperaments occur in 30%–80% of various manic-depressive populations (6, 8, 9).

As quoted above, Kraepelin believed that cyclothymia also existed in attenuated forms, without ever progressing to the fully developed illness. Thus, as currently used, cyclothymia refers to three related conditions: 1) affective temperaments seen among the biological relatives of manic-depressive probands, 2) premorbid affective traits predisposing to manic-depressive illness, and 3) subaffective or "abortive" forms of manic-depressive illness. Although sanctioned by tradition, the postulated relationship between certain affective personality types and manic-depressive illness can be challenged on the grounds of retrospective bias. In more recent years, armed with the methodological rigor of blind family interviews, Gershon and associates (10) have demonstrated an excess of cyclothymic and related personality disorders in the biological relatives of affectively ill probands. Such data provide general support for the hypothesized relationship between affective personality and affective illness.

However, a stronger test for the cyclothymic-bipolar continuum hypothesis should come from the reverse strategy. In other words, given a cyclothymic population selected without regard for family history, one should demonstrate in a prospective design that such patients share some of the crucial validating characteristics of the more typical or fully expressed forms of the illness. For instance, the following should be shown: 1) that such a cohort of cyclothymic probands comes from families "loaded" with the same kind of affective illness as classical bipolar manic-depressive illness; 2) that the spontaneous risk for developing frank and full-blown episodes of depression, hypomania, or mania is higher than that expected by chance and exceeds that of other personality disorders; 3) that, as in other forms of bipolar illness, the risk of developing hypomania is increased by the administration of tricyclic antidepressants and other drugs that mobilize catecholamines (11); and, finally, 4) that their response profile to lithium carbonate is comparable to the classical forms of the illness.

We were unable to locate any publication solely devoted to subaffective cyclothymic disorder studied in a

prospective design, yet we came across several reports advocating the use of lithium for such subaffective forms of the illness (12–14). Campbell's anecdotal case histories from the prelithium era remain the most detailed descriptions on the subject (15). Since the advent of lithium therapy for bipolar manic-depressive disorder, accurately describing and classifying these disorders has assumed major clinical and research significance. Dunner and associates (16) and Fieve and Dunner (17), for instance, proposed the following criteria for subtyping bipolar conditions: 1) bipolar I, hospitalized for mania; 2) bipolar II, hospitalized for depression with history of hypomania; and 3) other bipolar and cyclothymic personality, for those residual cases of bipolar illness hospitalized for neither depression nor mania. In order to subsume cyclothymic disorder under the general rubric of bipolar illness, one must first provide explicit phenomenological criteria to permit its reliable identification and then demonstrate that such a sample of cyclothymic probands drawn from a general psychiatric population shares other fundamental characteristics of the more classical forms of the illness.

In this article we will report our operational findings on a cohort of ambulatory cyclothymic probands studied in a prospective design and validate the manic-depressive nature of our case material on the basis of the first three principles outlined above. The pharmacological response profile of cyclothymic disorder to lithium carbonate will be presented in another communication.

PATIENTS AND METHOD

Screening of Patients

The study began 3 years ago when, over a period of 15 months, we screened about 500 ambulatory psychiatric patients who had never been hospitalized for depression, hypomania, or mania in order to identify cases of cyclothymic temperament. Forty-six patients, representing roughly one-tenth of the population under study, were selected.

Initially, we identified cyclothymic patients on the bases of our intuitive clinical impression that these patients represented incomplete forms of bipolar illness. They exhibited some features of both hypomania and depression as outlined in the criteria of Feighner and associates (18), but they failed to meet the sustained duration and/or the syndromal criteria for these disorders.

The cyclothymic patients came to psychiatric attention because of various personality maladjustments; the affective basis of their dysfunction became evident only after intensive clinical evaluation. Although the patients experienced considerable subjective distress, their primary reasons for seeking psychiatric help were in all cases related to serious problems in interpersonal, scholastic, or vocational areas. Therefore, it is not surprising that they had previously received the entire gamut of *DSM-II* personality labels, such as hysterical, emotionally unstable, explosive, passive-aggressive, sociopathic, inadequate, narcissistic, borderline, or obsessive-compulsive (19). Histrionic and sociopathic traits were noted in about two-thirds of the sample.

To avoid biasing our sample, we did not use family history of proven bipolar illness as a diagnostic aid.

Spitzer and associates (20, 21) stipulated that cyclothymic personality is an intermittent type of affective illness characterized by "recurrent periods of depression lasting at least a few days alternating with similar periods of clearly better than normal mood" (20, p. 25). We found that exclusive reliance on either depressed or elated mood provided many false positives. For instance, many patients who satisfied the Feighner criteria for Briquet's disorder (hysteria) and antisocial personality (18) frequently reported such mood swings. Therefore, we required the presence of unequivocal behavioral manifestations with the mood changes. (Patients who reported mood swings but did not exhibit behavioral signs were classified as "pseudocyclothymic.")

The population we selected and prospectively examined has given us the opportunity to identify the most striking clinical features derived from formal psychotherapeutic sessions and from interviews in which we collected systematic demographic, developmental, phenomenological, vocational, and interpersonal data. We undertook an extensive phenomenological and biographical analysis of each patient in long-term (6–12 months) weekly or biweekly psychotherapeutic sessions. The unpredictable mood swings, the dramatic shifts in behavior from day to day, and the tempestuous nature of object relations in these patients had produced multiple episodes of romantic breakups or marital failure. Therapy therefore focused on dyadic interactions.

Follow-Up

The patients were prospectively followed over a 2–3-year period. When clinically warranted, 54% received tricyclic antidepressants for brief periods of several weeks and/or lithium carbonate later during follow-up for periods ranging from 6–18 months.

Throughout the period of prospective observation, mania and depression were recorded on the basis of the Feighner criteria (18) by clinicians who were blind to the previous diagnosis of cyclothymia. Differentiating hypomania from mania is a matter of convention. Dunner and associates (16) distinguished hypomania (bipolar II) from mania (bipolar I) on the basis of hospitalization, but Spitzer and associates (20) required a shorter duration and one less symptom from the Feighner list for mania in the differential assignment of patients to one category or the other. Because mania is the more severe form of the two, in our view the presence of any of the following marked the transition from hypomania to mania: 1) general changes in demeanor from pleasant cheerfulness to sustained

querulous belligerence; 2) presence of affective delusions or hallucinations; and 3) serious social impairment that might require hospitalization.

Control Groups

We used two control groups. One was composed of 50 patients with bipolar I disease with a definite history of mania. By excluding bipolar II (hospitalized for depression) patients from this control group, we provided an unequivocal sample of classical bipolar I manic-depressive patients for comparison.

The other control group was composed of the 50 patients whom we had identified as pseudocyclothymic. These patients had various kinds of personality disorders and were superficially similar to the experimental group in that they reported frequent mood swings in the direction of both elation and dysphoria. However, they did not manifest the behavioral characteristics seen in the true cyclothymic probands.

Both control groups were randomly selected from consecutive admissions into our mood clinic during the same period when the cyclothymic probands were being screened. Because we were interested in a comparative analysis, we specifically did not control for age at first psychiatric presentation, sex, race, or social class. Actually, these demographic data turned out to be quite comparable and will not be further mentioned in this report. About 60% of both control groups received tricyclic antidepressants for several weeks or months; the bipolar I group was ultimately maintained on lithium carbonate. As with the experimental group, individual and/or couples therapy were provided for interpersonal conflicts.

Family History

Family history was obtained in a blind fashion according to the method of Winokur as incorporated into the family history-research diagnostic criteria (FH-RDC) (22). History of affective illness in first-degree biological relatives was obtained from at least two of the following sources: 1) the affected family member, when accessible; 2) records, facilitated by the fact that about 35% of the affected relatives were patients in our clinic; and 3) the spouse, sibling, parent, or children of the affected family member. Because cyclothymia represents the dependent variable in this study, family history was coded positive only for definite unipolar and definite bipolar biological relatives as well as for unequivocal suicides.

We used the chi-square test with Yates' correction for continuity when appropriate. Informed consent was obtained from all patients who participated in the study.

RESULTS

Demographic Features

Thirty-eight percent of the cyclothymic sample were men and 62% were women; 10% were black and 90% were white; there was an approximately equal distribution of Hollingshead's classes II–IV (23). The age range at first psychiatric presentation was 15–45, with a preponderance of patients between the ages of 15 and 25. The salient clinical features of the sample of cyclothymic patients are outlined below.

General Criteria for Cyclothymia

As seen in our 46 patients, the disorder usually had its onset in the early or mid teens but in no instance later than early adulthood. However, despite significant psychopathology, several patients in our series did not seek psychiatric help until much later in life.

Typically, patients manifested recurrent and short cycles of depression and hypomania that clearly fell short of the full syndromal criteria for these disorders. These episodes, according to selection criteria, generally did not crystallize into the full syndromes of depression or hypomania, although they did so in about 10% of the cases. Again according to selection criteria, the episodes typically lasted a few days, rarely up to a week. Failure to meet the sustained duration criterion was the major reason for the fact that these patients were not assigned the diagnosis of definite manic-depressive illness. The episodes alternated with each other in an irregular fashion. Intervening even periods were rare, occurring in less than 10% of the cases. As a consequence, partial mixtures of the subsyndromes often appeared as mixed states of a few days' duration, with irritable and explosive mood in about 50% of the patients. The onset of episodes was generally unrelated to external events or circumstances, although the episodes provoked life events of a tempestuous nature in well over 75% of the patients.

Operationally Derived Phenomenological and Behavioral Criteria

Although each of the items listed below might suggest a personality disorder when viewed individually, the clustering of these signs and symptoms should alert the clinician to the possibility of an underlying affective disorder. Because patients usually manifest subsyndromes and mixed states, ordinarily each patient will not manifest more than several of the characteristic types of behavior that follow:

1. About 50% displayed irritable periods lasting a few days that did not crystallize into an anxiety syndrome. For instance, the autonomic signs and symptoms of anxiety were rarely observed.
2. Fifty percent suffered from explosive aggressive outbursts that were ego-dystonic and often followed by periods of guilty rumination. These features differentiate cyclothymia from hysteria and sociopathy, and the absence of amnesia serves to distinguish it from epilepsy.
3. Repeated buying sprees, financial extravagance, or financial disasters were seen in about 75% of the patients.
4. Repeated shifts occurred in line of work, study, interest, or future plans in about 50% of the patients.

These shifts created the impression that their lives were chains of improvident activities, yet there were usually no other observational signs of flagrant sociopathy.

5. Episodic or unexplained promiscuous behavior or extramarital affairs occurred in an ego-dystonic fashion, appeared self-defeating, and often led to self-reproach when the depressive swing supervened. These features, found in about 40% of the patients, distinguish cyclothymia from sociopathy.

6. Finally, 25% of the patients exhibited a pattern of joining new movements with impulsive zeal that rapidly changed to utter disillusionment. Thus they displayed a lower threshold for seduction by all kinds of recondite movements and eschatological cults.

The presence of the following criteria should help to establish the biphasic nature of cyclothymia. Again, such behavior occurred in a dissociated form, and each patient characteristically exhibited just a few of the behavior patterns listed: hypersomnia alternating with decreased need for sleep (75% of the patients); shaky self-esteem alternating between lack of self-confidence and naive or grandiose overconfidence (75%); marked unevenness in quantity and quality of productivity whether at work or in school, often associated with unusual self-imposed working hours (75%); periods of mental confusion and apathy alternating with periods of sharpened creative thinking (50%); uninhibited people-seeking alternating with introverted self-absorption (50%); and an alternating pattern of drug abuse (stimulants and psychedelics alternating with sedative-hypnotic drugs) or dipsomania. Drug and alcohol abuse, which occurred in about 50% of the cases, represented either attempts at self-treatment or the self-indulgence that characterized the "up" periods.

Illustrative Case History

Case 1. A 29-year-old man was referred by his ex-wife for psychiatric evaluation. After 7 years of marriage they had just been divorced for the second time as a result of his many extramarital affairs. During their second marriage, he had undergone 2 years of outpatient analytical treatment to alter his "narcissistic personality makeup." Shortly after the second divorce, the wife went to graduate school to train as a social worker; there she became acquainted with descriptions of manic-depressive illness. She started experiencing guilt feelings because she felt that her husband might have been sick rather than "simply refusing to grow up." After many months of persistent effort, she finally succeeded in getting her ex-husband to go to the psychiatrist who had lectured to her class.

The patient had 3–4-day periods of "hypersexuality" during which he would sleep 4–5 hours a night and demand frequent intercourse. This was enjoyable to his wife during the first year of their marriage, but then she started experiencing discomfort, which was further compounded by her endometriosis. He then started frequenting bars in order to satisfy his "satyriacal needs." At other times he was intermittently lethargic or irritable, indulged in alcohol, slept 8–9 hours a day, and neglected his wife sexually. He was employed as an architect and during his "up" periods he would sometimes go to his office at 4:00 A.M. on weekends; during his "down" periods he would accomplish very little and resort to the use of amphetamines to keep going. He felt that what he termed his "naturally occurring up periods" were superior to "artificial speeding."

His employer valued him because he developed outstanding and creative projects at certain times of the year, even though his overall yearly output was considerably less than that of his colleagues. He was quite unpredictable in many areas; for instance, during a vacation, while his wife slept in a motel he took off from Miami to New York and returned the following afternoon. The patient denied subjectively experiencing mood swings; he was only aware of being "active and up" or "lazy and down." He stated that during his "up" periods he felt driven to do "crazy" things, such as reading *Time* magazine from cover to cover, including all the ads. He was known to be generous and showered his wife and lovers with expensive jewelry.

He had no biological relative who had received psychiatric treatment, but a maternal uncle had committed suicide in his mid-40s after having lived "a wild life of luxury and lechery." This patient's short cycles were evened out with a 3-month trial of lithium, and the couple married for the third time. For a while his wife complained that sex relations occurred far too infrequently, but 6 months of couples therapy restored conjugal homeostasis. The patient is still creative, but his productivity is evenly distributed throughout the year and he no longer uses amphetamines.

This case illustrates some of the cardinal features of cyclothymic disorder: presentation as a personality problem resulting in repeated conjugal failure; nonprominence of the affective symptoms; a clearly biphasic nature of the symptoms; short cycles; episodic and alternating pattern of drug abuse; and self-imposed hours of work and cyclicity of productivity.

We are grateful to this patient's wife for bringing him for psychiatric consultation. He was our first patient in this series on cyclothymia and alerted us to the possibility that manic-depressive illness may manifest itself in subtle and disguised forms.

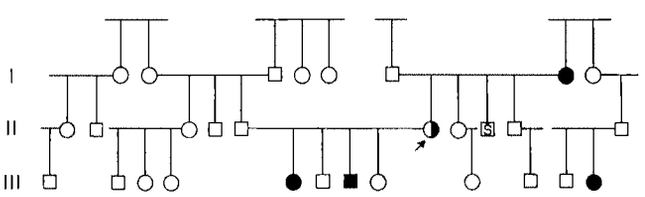
Family History Characteristics

Table 1 summarizes the family history characteristics of the experimental group compared with the two control groups. The cyclothymic patients and bipolar I patients have very similar patterns of familial incidence of suicide, unipolar disorder, bipolar disorder, and total incidence of affective illness in two consecutive generations. In contrast, the incidence of these same disorders (with the exception of unipolar disorder) is negligible in the families of the pseudocyclothymic patients.

More importantly, 5 of our cyclothymic probands appeared to provide the link for the transmission of the illness in three consecutive generations, as shown in the sample pedigree in figure 1. In this pedigree a cyclothymic prepositus is shown in generation II. Her husband's side of the family is completely free of affective illness; therefore, the prepositus is the only possible intermediary for the transmission of manic-depressive illness from her mother in generation I to her children in generation III.

TABLE 1
History of Affective Illness in Biological Relatives of 46 Cyclothymic Patients, 50 Bipolar I Patients, and 50 Pseudocyclothymic Patients

Affective Illness in Relative	Cyclothymic Patients		Bipolar I Patients		Pseudocyclothymic Patients		Significance*
	Number	Percent	Number	Percent	Number	Percent	
Unipolar	7	15	11	22	5	10	n.s.
Bipolar	14	30	13	26	1	2	p<.01
Suicide	10	22	9	18	2	4	p<.03
Total**	30	65	28	56	7	14	p<.001



*The cyclothymic patients and the bipolar I patients were very similar in these comparisons. The p values represent the cyclothymic and bipolar groups individually compared with the pseudocyclothymic group. In all cases the p values were the same for both comparisons.
**The total number of patients with a positive family history of affective illness is less than the sum of the first three rows in each column because some cases of suicide were from the ranks of either unipolar or bipolar patients.

TABLE 2
Affective Episodes of 46 Cyclothymic Patients and 50 Pseudocyclothymic Patients During Drug-Free Periods of Follow-Up

Affective Episode	Cyclothymic Patients		Pseudocyclothymic Patients		Significance
	Number	Percent	Number	Percent	
Depression	11	24	2	4	p<.02
Hypomania and mania	10	22	0		p<.01
Total*	16	35	2	4	p<.001

*The total number of patients is less than the number of episodes shown in the first rows of both columns because several patients experienced both depression and hypomania.

FIGURE 1
Pedigree of 1 Cyclothymic Patient*

*As the figure shows, the cyclothymic patient served as the genetic link in this three-generational pedigree with manic-depressive illness. The Roman numerals to the left of the figure indicate first, second, and third generations; ■ and ● = manic-depressive male and female family members; □ and ○ = unaffected male and female family members; S = completed suicide in a male family member; and ◑ = cyclothymic prepositus.

Drug-Free Follow-Up

As shown in table 2, 16 of the 46 patients in the experimental group (35%) progressed to spontaneous affective episodes that met the full duration and syndromal criteria for hypomania or depression. Eleven developed depression, 7 developed hypomania, and 3 progressed to mania. These episodes were spontaneous in the sense that they occurred during medication-free periods. Therefore, 3 patients could be reclassified as bipolar I (frank episode of mania) and 13 patients as bipolar II (frank episode of depression, hypomania, or both). These episodes occurred, on the average, 1–2 years after the index diagnosis of cyclothymia and 2–4 years after patients first came for psychiatric help. By comparison, only 2 of the 50 patients classified as pseudocyclothymic (5%) developed frank depression, satisfying the duration and syndromal criteria, and none developed hypomania or mania. The two groups differed significantly in all of these respects, but the most important difference was seen in the cyclothymic probands' increased vulnerability to hypomania or mania (p<.01). It is difficult to determine how many additional patients from the cyclothymic group would have developed full affective episodes if lithium had been withheld.

"Pharmacological" Hypomania

Brief hypomanic episodes during the course of tricyclic therapy occurred at a similar rate in the cyclothymic and bipolar I patients. Thus 14 of 40 bipolar I patients (35%) and 11 of 25 cyclothymic patients (44%) experienced hypomania, but none of the pseudocyclothymic patients receiving tricyclics did. The differences between the pseudocyclothymic versus both the cyclothymic and bipolar I groups are highly significant (p<.001). Whether the episodes under consideration were pharmacologically induced or would have occurred anyway is difficult to determine; although brief in duration, they were phenomenologically identical to the naturally occurring episodes and tended to subside after the antidepressant was discontinued. The exclusive occurrence of this response to tricyclics in both cyclothymic and bipolar I groups in comparison with the pseudocyclothymic group suggests that the bipolar I and cyclothymic

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE LIBRARY

patients shared important phenomenological and pharmacological response profiles.

DISCUSSION

Kraepelin described four overlapping temperaments, identified either by premorbid traits in manic-depressive patients or by constitutional peculiarities in their biological relatives (1). These were the depressive, the hypomanic, and the irritable (a simultaneously occurring mixed form of the first two) temperaments, plus the cyclothymic temperament proper (an alternating pattern of the first two types). Kurt Schneider later substituted "dysthymic" for the depressive and "hyperthymic" for the hypomanic personalities, respectively (3).

Our selection criteria—requiring biphasic clinical features—excluded pure dysthymic subjects, who would currently be subsumed under the rubric of depressive characters. We are studying a population of dysthymic patients and will report our findings elsewhere. As to the other subtypes, we discovered that hyperthymic patients did not account for more than 2 patients, i.e., 5% of the total sample; moreover, these 2 patients occasionally experienced depression. Similarly, the irritable group seemed to represent just one phase of the overall cyclothymia rather than a separate category. These findings are analogous to the relative rarity of pure recurrent mania (6, 9) and the occurrence of mixed states as transitions from mania to depression (1, 24) in the full-blown forms of manic-depressive illness.

There are two major difficulties in identifying "true" cyclothymic patients. Many hysterical and sociopathic patients report mood swings in both elated and dysphoric directions. Also, characterological cases of unipolar depression sometimes masquerade as moody states because their occasional normal periods are reported as "highs" relative to their depressive states. To avoid such pitfalls one must document clear-cut behavioral changes consonant with the mood and insist on the presence of definite biphasic behavioral changes.

Klein and associates (25) described a type of personality that occurs predominantly in young women and is characterized by wide mood fluctuations on an hour-to-hour or day-to-day basis. They distinguished such "emotionally unstable personalities" from cyclothymic personalities on the grounds that the former are "irresponsible, hedonistic, extractive and exploitative," while the latter "pursue socially acceptable and valued goals." We cannot make such a dichotomy because our patients exhibited mixtures of both patterns; this finding is actually in line with Kraepelin's classical descriptions (1). Dunner (26) stated that the syndrome identified by Klein's group is the same as bipolar II disorder. Since Klein's group did not provide family history data, it is hard to resolve this difference of nosological assignment for the emotionally unstable group. We obtained family history data on our cohort of 46 cyclothymic patients; therefore, we can address this question with some degree of rigor. Our findings provide strong support for the existence of a group of attenuated, cyclothymic, or subaffective disorders that merge imperceptibly with the bipolar II (and sometimes bipolar I) forms of manic-depressive illness. The evidence is as follows:

1. Phenomenologically, cyclothymic disorder presented with characteristic signs and symptoms that clustered into incomplete and short cycles with definite evidence for a biphasic course.
2. In terms of family history, the distribution of affectively disordered biological relatives in the pedigrees of cyclothymic and bipolar I probands was almost identical. Moreover, in several pedigrees the cyclothymic proband provided the only possible link for transmitting the illness in three-generational perspective; this is perhaps the most compelling evidence for considering cyclothymic disorder as an attenuated form of the more classic manic-depressive illness. Comparison with the pseudocyclothymic group of personality disorders indicated that family history of bipolar illness is the most useful familial predictor of true cyclothymia.
3. In longitudinal perspective, almost one-third of the cyclothymic group progressed into the full-blown clinical picture of manic-depressive illness. However, ours was a psychiatric sample; conceivably such progression may occur less frequently in a general population sample.
4. Pharmacologically, the frequency of hypomanic episodes during tricyclic therapy was very similar in the cyclothymic and bipolar I probands.

Our selection criteria are further validated because control probands with personality disorder and mood swings but without behavioral manifestations of a biphasic nature displayed none of the characteristics noted above. Therefore, to diagnose cyclothymic disorder, major emphasis should be laid on the behavioral manifestations of the syndrome and not mood swings per se.

Of sociological relevance is the finding that cyclothymic patients, who comprised 10% of a nonhospitalized psychiatric population with mixed personality disorders, displayed a high incidence of promiscuous behavior and marital failure, financial disasters, heightened but uneven creativity and unstable employment records, an episodic pattern of drug and alcohol abuse, and a low threshold for seduction by various recondite cults and eschatological movements. Some psychiatrists have suggested that psychiatry should withdraw from the arena of problems of living represented by personality disorders (27). Our data, however, raise the possibility that some forms of minor social "deviance" may have their origin in attenuated, unrecognized, or masked forms of potentially treatable affective illness. The therapeutic fate of these patients with lithium carbonate will be presented elsewhere.

In closing, we wish to caution the reader that at the present time we do *not* advocate the routine diagnosis of cyclothymic disorder in everyday practice. The identification of this disorder should be contemplated only after in-depth phenomenological examination of individual patients seen in specialized affective disorder clinics where continuity of care and follow-up are provided by a team of experienced clinicians. The same caution applies even more stringently to lithium trials in such subaffective forms of manic-depressive illness.

Clinical Pharmacology of Phencyclidine Toxicity

BY CRAIG V. SHOWALTER, M.D., AND WILLIAM E. THORNTON, M.D.

Phencyclidine appears to be unique in action compared with other psychedelic drugs, and its effects are less dependent upon the individual's personality than are the effects of LSD or mescaline. The authors discuss the sensory, psychological, and behavioral symptoms of phencyclidine intoxication. Most cases are of short duration and the only treatment necessary may be observation together with minimal stimulation and diazepam. However, prolonged and severe behavioral disturbances, exaggeration of preexisting thought disorder, and serious medical complications commonly occur and must be considered in the treatment plan.

PRIMARY CARE physicians throughout the United States are being confronted by patients intoxicated by a relatively new psychedelic drug, phencyclidine, 1-(1-phenylcyclohexyl) piperidine (Sernyl, Sernylan). While phencyclidine is the parent compound of the intravenous anesthetic ketamine, it was discarded as an anesthetic agent for humans and is now legally sold only to licensed veterinarians for use as an immobilizing agent for subhuman primates. In its illegal forms it is known as PCP, "angel dust," and a variety of other street names. As with many other popular mind-altering drugs, phencyclidine appeared on the West Coast in the 1960s and from there spread throughout the country.

Although its many unpleasant side effects initially discouraged its widespread use, recently the manufacture and use of illicit phencyclidine have become extensive. Phencyclidine is frequently a drug of choice, especially when it is sprinkled over marijuana and smoked. It is frequently misrepresented by sellers as TIC or THC (tetrahydrocannabinol, which is the active ingredient in marijuana and is probably not found in illicit circles), mescaline, peyote, psilocybin, and a variety of synthetic psychoactive substances. Misrepresentation of phencyclidine is widespread because of its undesirable side effects, its ready availability compared with what it is represented to be, and the wishful belief of the drug user that he or she is experiencing a more exotic natural drug such as mescaline or psilocybin. These latter drugs are infrequently found in analyses of street drug samples. Such deception adds to the physician's difficulty in making an accurate diagnosis in the case of a suspected drug intoxication, even with a cooperative patient or his well-meaning friends.

When correctly synthesized, phencyclidine is a glistening white, crystalline powder, readily soluble in both water and alcohol. In veterinary medicine the liquid injectable form is used, although the powder is still legally manufactured. Phencyclidine produced by underground laboratories appears in liquid form, as an off-white powder, or in tablets of various sizes and colors and of variable purities. The powder may be found in capsules, foil, or any similar makeshift containers.

Since the ingredients for phencyclidine are readily available and synthesis is relatively simple, "basement" chemists have become involved in its production on a large scale and at great profit. The production of a pound of phencyclidine requires about a $75 investment in raw chemicals and can bring street sales in excess of $20,000. In 1974, seizure of an underground laboratory in Maryland yielded 90 pounds of phencyclidine, half in powder and half in liquid form, and a similar confiscation in Detroit shut down production of an estimated one million phencyclidine tablets a week. With production and profits of this magnitude it is not surprising that this drug has spread across the United States as well as Canada and Europe. A recent study conducted in Detroit (1) reported that phencyclidine was the most frequently used drug in 1,000 cases of substance intoxication. Several cases of accidental ingestion of phencyclidine by children have been reported in the literature (2, 3).

SENSORY AND PSYCHOLOGICAL MANIFESTATIONS

While phencyclidine is often labeled a hallucinogen, it is questionable whether true hallucinations occur with its use. In fact, some researchers (4, 5) have used the absence of hallucinations to distinguish the effects of this drug from those of LSD and mescaline. Phencyclidine appears to be unique in action compared with other psychedelic drugs, and its effects are less dependent upon the individual's personality than are the effects of either LSD or mescaline. Individuals who have taken phencyclidine do not describe the in-

Dr. Showalter is Clinical Director, Substance Abuse Services, Inc., 1439 South Michigan Ave., Chicago, Ill. 60605. At the time this work was done Dr. Thornton was Assistant Professor of Psychiatry, Abraham Lincoln School of Medicine, University of Illinois, and Chief, Consultation-Liaison and Emergency Psychiatric Services, University of Illinois Hospitals, Chicago, Ill. He is now Associate Professor, Department of Family Practice and Psychiatry, Medical University of South Carolina, Charleston, S.C.

creased ability for self-observation or the kaleidoscopic visual hallucinations reported by users of the more classic hallucinogenic substances (6). On the contrary, the phencyclidine experience is more likely to be unpleasant, with impaired clarity of thought, marked anxiety, and psychosis.

A consistent sequence of psychological impairment has been found when the drug is given in an experimental situation (4). The first symptoms to appear are changes in body image related to parts of the body or to the total body image. Some subjects describe their limbs as elongated or floating away from their bodies, while others report alternate contraction and expansion of body size. It is likely that it is these body image distortions that are incorrectly interpreted as hallucinations by both patient and physician. Progressive feelings of depersonalization, isolation, and depression frequently follow and often persist for hours. Anxiety is one of the most common findings and is often the most severe presenting symptom. Disorganization of thought with concrete thinking, blocking, and neologisms may be present. With increased dosages the unpleasant psychological effects are likely to increase. Negativism, hostility, and apathy are prominent and sometimes progress to a cataleptic state—a state of "dissociative anesthesia" during which major and minor surgical procedures were performed during the drug's early clinical trials. Coma, convulsions, and death, usually attributed to respiratory failure, may follow. Additional clinical findings include vertigo, diaphoresis, flushing, and frequently nausea and vomiting. In spite of these seemingly unpleasant effects, phencyclidine is becoming increasingly popular among drug users, with parenteral administration becoming more frequent.

Morgenstern and associates (7) tested subjects given phencyclidine orally and found sensory impairment in all modalities tested over the first two hours. Some modalities may be affected more than others, with two-point discrimination and touch being most affected, followed by impairment in visual fields, auditory acuity, sense of position, taste, and visual acuity. Clinical observation reveals that a general sensory impairment precedes the drug's psychological effects. The disturbances resulting from phencyclidine intoxication apparently require exteroceptive input for their arousal, and the psychological effects of the drug may be attributed at least in part to disturbances in sensory input or impairment of the ability to integrate sensory input into meaningful behavior (7–9). This theory has been supported experimentally by some improvement in phencyclidine intoxication with isolation and greater improvement with sensory deprivation (10–12). Accordingly, "talking down" the phencyclidine-intoxicated patient has not had the success attributed to the use of this technique with the LSD-intoxicated patient.

A number of studies (4, 9, 13, 14) have compared the effects of phencyclidine to psychotic processes. Several of the investigators concluded that phencyclidine characteristically produces disturbances similar to the primary symptoms of schizophrenia (such as blocking, impaired motor performance, and disruption of abstract and sequential thinking), while substances such as mescaline and LSD mimic the more secondary symptoms of schizophrenia (such as hallucinations). Phencyclidine does produce severe impairment of symbolic cognition (proverb interpretation) and of sequential thinking (serial sevens). This level of impairment is quite similar to that of a group of patients diagnosed as schizophrenic (13). Schizophrenic patients given a single dose of phencyclidine have experienced an intensification of their thought disorder lasting from several days to several weeks (4). LSD does not generally produce these effects in schizophrenic patients. The prolonged effect of phencyclidine ingestion is not limited to patients with preexisting thought disorders. Furthermore, some researchers (15) have reported a delay of several days before the appearance of severe behavioral toxicity. Anterograde amnesia frequently occurs following administration of the drug.

PHYSIOLOGICAL MANIFESTATIONS

The psychological effects of phencyclidine intoxication are accompanied by many abnormal neurological findings (3, 15). With lower doses the user experiences a giddy, drunken feeling with euphoria resembling ethyl alcohol intoxication, although marked anxiety and emotional outbursts are frequently seen in the emergency treatment situation. Ataxia, slurred speech, and tremulousness with increased deep tendon reflexes and clonic movements are common. Paresthesias and analgesia, especially of the face and extremities, and muscle weakness may also occur. As with other responses to phencyclidine, neuromuscular effects are dose related. Inebriated behavior, paresthesias, and analgesia are lower-dose phenomena, and there is a progression to anesthesia and catatonic-like posturing with higher doses. When toxic levels are reached these effects may progress to myoclonic movements, convulsions, and coma.

In early clinical trials of phencyclidine, muscle rigidity was common and was a major obstacle to its acceptance as an anesthetic. Reflex activity is exaggerated with low doses, but with high doses there is an eventual depression of reflexes (polysynaptic reflexes are affected more than monosynaptic reflexes) (16). Pharyngeal and laryngeal reflexes may remain active, thus increasing the risk of laryngospasm, bronchospasm, and coughing (17, 18). This, together with hypertonicity of facial and neck muscles, will pose serious difficulties should tracheal intubation become necessary. Eye signs of phencyclidine intoxication are many and nonspecific. Pupils are usually either constricted or normal. Nystagmus is frequently found, and diplopia, decreased pupillary light reflexes, absent corneal reflexes, and bilateral ptosis are often seen (19, 20). EEG changes occur predominantly in

the occipital, temporal, and parietal regions and are characterized in man by slowing, particularly to theta activity, but becoming more diffuse with high doses (21). These changes are different from those that occur during sleep or use of barbiturates (16). It has been suggested that phencyclidine specifically alters synaptic transmission in the brain (22). A number of studies have demonstrated altered concentrations of central neurohumoral transmitters after administration of phencyclidine (23–26). Areas of the central nervous system where phencyclidine is believed to act include the sensory cortex, thalamus, midbrain, and spinal cord (16).

Several other physiological manifestations of phencyclidine intoxication accompany the neuropsychiatric disturbances. Systolic and diastolic blood pressures are frequently elevated. In one series of tests, mean systolic elevations of 25.7 mm Hg and diastolic elevations of 19 mm Hg were reported (19); in another study systolic pressure ranged from 120–200 mm Hg and diastolic pressure from 60–110 mm Hg in high-dose ingestions (27). The pressor effects are not influenced by ganglionic blocking agents, adrenalectomy, decentralization, or pretreatment with reserpine but are at least partly reduced by adrenergic blocking drugs (28, 29). Ilett and associates (28) have suggested that the site of action of phencyclidine is the alpha adrenergic receptor; and they have demonstrated experimentally that phenoxybenzamine (Dibenzyline) and phentolamine (Regitine), alpha adrenergic blocking agents, markedly reduce or completely block the pressor response to phencyclidine. Phencyclidine also potentiates the pressor response to epinephrine, norepinephrine, and serotonin (16, 30). Hitner and associates (29) believe that the phencyclidine potentiation of catecholamines may be cocaine-like in inhibiting the neuronal reuptake of these transmitters. While the direct pressor effects of phencyclidine may last only 15–60 minutes, the pressor effects of the neurohumoral transmitters are enhanced for as long as an hour after the baseline blood pressure returns to normal (16).

Elevated blood pressure does not appear to be the result of increased cardiac output, since phencyclidine has been found to be a direct myocardial depressant. Marked reduction in the force of contraction and decreased rate of conduction have been demonstrated in isolated cardiac muscle (28). Tachyphylaxis to the pressor effects of phencyclidine develops rapidly (29). Sinus tachycardia, occasional arrhythmias, bradycardia, and hypotension have also been reported (17, 26, 31). With low dosages of phencyclidine, respiration is either unaffected or stimulated; higher dosages may result in respiratory depression, Cheyne-Stokes respiration, apnea, and respiratory arrest (3, 19).

Contrary to early and persistent reports, phencyclidine has been shown experimentally to have anticholinergic actions (32–34). The anticholinergic effects of phencyclidine are of rapid onset, of short duration, dose related, and considerably less potent than those of atropine. It is unlikely that mydriasis would be seen clinically. The anticholinergic effects may be demonstrated in isolated gut and striated muscle. Changes in body temperature have not been determined with certainty. Phencyclidine's anticholinergic action is believed to be by competitive antagonism through specific binding at the receptor site (32–34). Phencyclidine has been found to be a potent competitive inhibitor of butyrylcholinesterase (pseudocholinesterase) (32). Should surgery be necessary for the patient with phencyclidine intoxication, decreased pseudocholinesterase activity may prolong the paralyzing action of the depolarizing muscle relaxant succinylcholine. Prolonged apnea has occurred when the phencyclidine derivative ketamine was used with succinylcholine (35). No such prolonged effect was seen when ketamine was used in combination with nondepolarizing muscle relaxants.

Phencyclidine is rapidly metabolized in the liver by hydroxylation and the conjugates are excreted into the urine. Man excretes mainly the mono-4-hydroxypiperidine derivative. These metabolites are relatively weak and apparently do not contribute significantly to the pharmacological activity of the parent compound (16). In cases of phencyclidine poisoning, high concentrations of the unmetabolized drug have also been found in the urine (3). Hepatic drug metabolism is enhanced in animals after four days of treatment with phencyclidine (36), and tolerance to the effects of phencyclidine may develop with regular usage (37). Cross-tolerance of phencyclidine with other drugs has not been demonstrated. Acute hepatic cellular toxicity following phencyclidine use has not been reported at this time.

TREATMENT

Treatment of acute phencyclidine intoxication is often a psychiatric emergency, and there may be other serious medical complications as well. In one hospital study in a large metropolitan area (38), phencyclidine psychoses exceeded both schizophrenia and alcoholism as the cause for inpatient psychiatric admission. Evaluation of suspected cases of phencyclidine intoxication should rule out the possibility of other organic central nervous system pathology, a primary psychosis, or ingestion of another drug. Elevated blood pressure, frequently normal or stimulated respirations, and bizarre neurological and behavioral signs and symptoms help to distinguish phencyclidine intoxication from most narcotic and sedative overdoses. Methaqualone intoxication perhaps most closely resembles acute phencyclidine poisoning, especially in coma. A prolonged recovery phase and occasional delayed onset of behavioral disturbances may also lead one to suspect phencyclidine over many other psychedelic drugs.

The basis for treatment lies in a knowledge of the pharmacology of phencyclidine and its unique, dose-

related clinical manifestations. For the majority of the cases of low-dose intoxication, successful treatment may require only minimal stimulation for an hour or two, with observation to detect any changes requiring support. While talking down the anxious patient may be attempted, it often results in intensification of anxiety and agitation. Placing the patient in a quiet, dimly lit room has been our most successful approach. Parenteral diazepam is often useful in calming the patient and in treating myoclonus and seizures. It is doubtful whether there is any need for antipsychotic agents such as chlorpromazine, except perhaps in situations of severe behavioral disturbances or aggravation of preexisting thought disorders. Patients with such disorders will probably require hospitalization in a psychiatric unit. Therapeutic doses of phenothiazines have resulted in significant hypotension when used in the treatment of phencyclidine intoxication (27). In general, in cases of ingestion of unidentified drugs it is best to avoid phenothiazines and other drugs with anticholinergic properties. Illicit drugs are often adulterated with belladonna alkaloids, and phencyclidine itself has anticholinergic effects. A butyrophenone such as haloperidol is preferred when treatment with an antipsychotic drug is believed necessary.

The behavioral aspects of phencyclidine intoxication are most often the reason a patient is brought for treatment, but serious medical complications should be anticipated. To minimize serious and prolonged complications, gastric lavage is indicated in suspected cases of high-dose ingestion. Respiratory irregularities or arrest will require ventilatory support. Intubation may be difficult because of intact pharyngeal and laryngeal reflexes as well as muscle hypertonicity. Prolongation of the action of depolarizing muscle relaxants by phencyclidine should be a consideration in anesthetic management. The use of CNS stimulants in the management of respiratory depression or coma is controversial, but in our opinion the risk of increased cerebral hypoxia and resultant hypoxic seizures is too great with a drug that may inhibit respiratory response to the increased oxygen demands of the stimulant action.

Hypertension frequently occurs after phencyclidine ingestion, and treatment may sometimes be required. In view of experimental data that phencyclidine has direct pressor activity, an alpha adrenergic blocking agent such as phenoxybenzamine or phentolamine may be useful. In a case of severe hypertension after phencyclidine ingestion, the patient's blood pressure was successfully lowered with diazoxide (Hyperstat) (2). Renal function should be monitored since it has been reported that high doses of phencyclidine impede urinary output (30); at the same time hydration should be adequate to promote renal excretion of unmetabolized phencyclidine and its metabolites. Because high concentrations of phencyclidine are often found in the urine, a specimen should be sent to the laboratory for drug identification. Since many laboratories are not prepared to do analysis for phencyclidine and because of the delay in receiving a report when the test is done, treatment must begin with the working diagnosis.

CONCLUSIONS

In conclusion, the increasing availability and abuse of phencyclidine make consideration of this unique drug necessary in suspected cases of drug intoxication or in acute delirium states. Most such cases are of short duration and the only treatment necessary may be minimal stimulation, observation, and the use of diazepam. However, prolonged and severe behavioral disturbances, exaggeration of preexisting thought disorders, and serious medical complications are commonly found and must be considered in the treatment plan.

Rape: Power, Anger, and Sexuality

BY A. NICHOLAS GROTH, PH.D., ANN WOLBERT BURGESS, R.N., D.N.SC., AND LYNDA LYTLE HOLMSTROM, PH.D.

Accounts from both offenders and victims of what occurs during a rape suggest that issues of power, anger, and sexuality are important in understanding the rapist's behavior. All three issues seem to operate in every rape, but the proportion varies and one issue seems to dominate in each instance. The authors ranked accounts from 133 offenders and 92 victims for the dominant issue and found that the offenses could be categorized as power rape (sexuality used primarily to express power) or anger rape (use of sexuality to express anger). There were no rapes in which sex was the dominant issue; sexuality was always in the service of other, nonsexual needs.

WITHIN the last few years, increasing awareness of and concern for the rape victim has become evident in this country. However, relatively little attention has been directed toward understanding the rapist and the motivations underlying his offense. A major handicap in this regard has been access to offender populations; rapists rarely report voluntarily to mental health clinics, and the conviction rate for rape is extremely low. In commenting on the professional literature on the rapist, Abel and colleagues (1) pointed to the lack of accessibility of offenders for evaluation and treatment and the failure of the professional community to develop effective and efficient models of treatment. Pacht (2) believes that until a sufficient number of controlled research studies are completed, ineffective approaches may be used in efforts to provide appropriate treatment for the rapist.

Research in the field of sexual assault is multidisciplinary (3). Amir (4), in his survey of several hundred rape cases handled by the Philadelphia Police Department, discussed the role relationship between victim and offender. MacDonald (5) evaluated rape cases in the Denver area on such epidemiological factors as time of day, season, and the relationship of victim and offender. The operational behavior approach to studying deviant sexual behavior has been undertaken by Abel and Blanchard (6), Barlow (7), Evans (8), and Marshall (9). Rada (10) devised a combined social and psychiatric diagnostic classification for use with rapists in a clinical setting. In the psychological literature, the motivational aims and needs of the rapist have been described by Guttmacher and Weihofen (11), Gebhardt and associates (12), and Cohen and colleagues (13). Sociologists and criminologists have reported on the issue of power and dominance as factors in rape (14) and on rape as social control (15–18)[1]; Gelles examined power, sex, and violence in marital rape (19).

To date, few reported comparative data have been available on the phenomenon of rape from the experiential standpoint of both the offender and the victim. This paper examines forcible rape through an analysis of separate offender and victim accounts and suggests a clinical typology of rape derived from these data.

METHOD

Written into the General Laws of Massachusetts is a statute (Chapter 123A) that provides for diagnostic evaluation of anyone convicted of sexual assault in regard to the probability of repetition and dangerousness. If it is adjudicated likely that the offender will repeat his offense and in so doing jeopardize the physical safety of his victim, he may be civilly committed for an indefinite period of from one day to life (in lieu of or in addition to a prison sentence) to a special maximum security treatment center operated by the state Department of Mental Health. The clinical and statistical data reported in this paper in regard to the offender are derived from a random sample collected by Groth of 133 convicted rapists committed for clinical assessment to the Massachusetts Center for the Diagnosis and Treatment of Sexually Dangerous Persons.

The victim sample population is derived from a one-year counseling and research study conducted at the Boston City Hospital that included all persons admitted to the emergency service with the chief complaint, "I've been raped." Burgess and Holmstrom clinically assessed the 146 victims of sexual assault according to three categories: rape trauma, accessory to sex, and

Dr. Groth is Director, Forensic Mental Health Department, Harrington Mental Health Clinic, Southbridge, Mass. Dr. Burgess is Professor of Nursing and Dr. Holmstrom is Chairperson and Associate Professor, Department of Sociology, Boston College, Chestnut Hill, Mass. 02167. Address reprint requests to Dr. Burgess.

The authors wish to acknowledge the clinical work of Murray L. Cohen, Ph.D., Boston University, on the psychology of rape, which has contributed to their conceptualization of sexual assault.

[1]An abridged version of Bart's paper (18) was printed in the June 1975 issue of *Viva* magazine.

sex-stress situation (20). The 92 adult rape victims from that study comprise the sample for this paper.

The offenses committed by the offender population and those experienced by the victim population were congruent in time, but they were unrelated in that none of the women in the sample were victims of the offenders studied.

The descriptions of the rape assaults given by offenders and victims were analyzed in order to develop a typology of rape. A major intent was to see if the accounts provided by the two groups could be encompassed within one conceptual framework.

RESULTS

Typology of Rape

One of the most basic observations one can make about rapists is that they are not all alike. Similar acts are performed for different reasons or different acts serve similar purposes. Our clinical experience with convicted offenders and with victims of reported sexual assault has shown that in *all* cases of forcible rape three components are present: power, anger, and sexuality. The hierarchy and interrelationships among these three factors, together with the relative intensity with which each is experienced and the variety of ways in which each is expressed, may vary, but there is sufficient clustering to indicate distinguishable patterns of rape. We have found that either power or anger dominates and that rape, rather than being primarily an expression of sexual desire, is, in fact, the use of sexuality to express issues of power and anger. Rape, then, is a pseudo-sexual act, a pattern of sexual behavior that is concerned much more with status, aggression, control, and dominance than with sensual pleasure or sexual satisfaction. It is sexual behavior in the service of nonsexual needs and, in this sense, is clearly a sexual deviation (21).

Power rape. In this type of assault, the offender seeks power and control over his victim through intimidation by means of a weapon, physical force, or threat of bodily harm. Physical aggression is used to overpower and subdue the victim and is directed toward achieving submission. The aim of the assault usually is to effect sexual intercourse as evidence of conquest; to accomplish this, often the victim is kidnapped, tied up, or otherwise rendered helpless.

This type of offender often shows little skill in negotiating interpersonal relationships and feels inadequate in both sexual and nonsexual areas of his life. Because he has few other avenues of personal expression, sexuality becomes the core of his self-image and self-esteem. Rape is the means by which he reassures himself of his sexual adequacy and identity, of his strength and potency.

Since it is a test of his competency, the rape experience for this offender is one of anxiety, excitement, and anticipated pleasure. The assault is premeditated and preceded by an obsessional fantasy in which his victim may initially resist him but, once overpowered, will submit gratefully to his sexual embrace. She then will be so impressed with his sexual abilities that she will respond with wild abandon. In reality, this offender may be handicapped by impotency or premature ejaculation (22). Even if he is not, he still tends to find little sexual satisfaction in the rape. The assault is disappointing because it never lives up to his fantasy.

Often he must convince himself that his victim became "turned on" to him, really wanted sex but could not admit it, and clearly consented nonverbally and enjoyed the sexual contact. However, at some level he realizes that he has not found what he is looking for: something he cannot clearly define is lacking. He does not feel reassured by either his own performance or his victim's response and therefore must go out and find another victim—this time the "right one."

The offenses become repetitive and compulsive. The amount of force used in the assault may vary and there may be an increase in aggression as the offender becomes more desperate to achieve that indefinable experience that continues to elude him. Usually there is no conscious intent on the part of this offender to hurt or degrade his victim. The aim is to have complete control over her so that she has no say in the matter. She will be submissive and gratify his sexual demands.

This rape may be understood as the result of an endogenous developmental psychological crisis precipitated by some perceived challenge from a female or threat from a male that activates the offender's feelings of inadequacy and insecurity (23). Rape is the way in which this type of person asserts his identity, potency, mastery, strength, and dominance and denies his feelings of worthlessness, rejection, helplessness, inadequacy, and vulnerability.

The victim of this assault is typically within the same age group as the offender or younger. Hospital examination generally shows minimum or inconclusive evidence of physical or sexual injury, and clinical evidence of intercourse—presence of motile sperm—may be absent. The victim often reports being questioned by the offender regarding her sexaul life, her reaction to his sexual performance, and her identity, with the implication of expected further contact. The victim is fearful that the offender will attempt to return and is upset about the forced conversation and sexual assault. Her coping behavior is often in the service of trying to talk her way out of the rape or resisting intimidation initially by being assertive and confrontational.

Rapists who fall into the power assault category can be subdivided on the basis of whether the major goal in the offense is assertion or reassurance.

The *power-assertive rapist* regards rape as an expression of his virility and mastery and dominance. He feels entitled to "take it" or sees sexual domination as a way of keeping "his" women in line. The rape is a reflection of the inadequacy he experiences in terms of

his sense of identity and effectiveness. Case vignettes below illustrate this subtype.

Mr. A, a 20-year-old single man on leave from the Coast Guard, picked up an 18-year-old hitchhiker and drove her to a secluded beach. She begged to be let go, but he grabbed her, saying, "You don't want to get hurt, baby—you want to get laid. You want it as much as I do." He forced her to submit to intercourse and then offered to buy her dinner. While out on bail he committed an identical offense. As an adolescent, he had been involved in a number of sexual incidents involving exhibitionism and sexual play with children and was treated at a local mental health clinic. As an adult he had no steady girlfriends and while in the service was living with and being supported by a 30-year-old man in exchange for sexual favors. However, he does not regard himself as a homosexual. He committed two previous rapes for which he was never apprehended; his only other arrests were for motor vehicle violations. Although he is of above-average intelligence, his academic and vocational accomplishments were mediocre, and the only activity he had pursued with any diligence was body-building.

Ms. B is a 45-year-old divorced woman. A former boyfriend came by her home with a bottle of gin and asked her to share a drink with him. She agreed. Later that evening she refused to have sex with him and her account of what happened follows: "He messed me over the street way. I'm not supposed to tell. He said he'd beat me if I tell and he gave me a sample tonight to show me. They work you over to control you so they can have you sexually any time they want. He hit me on the ear, pulled my hair, hit me in the back by my kidneys—very strategic. But it's not the physical part that's the thing. It's mental—to control you."

The *power-reassurance rapist* commits the offense in an effort to resolve disturbing doubts about his sexual adequacy and masculinity. He wants to place a woman in a helpless, controlled position in which she cannot refuse or reject him, thereby shoring up his failing sense of worth and adequacy.

Mr. C is a 24-year-old married man who pleaded guilty to six charges of rape. In every case he approached the victim with a gun in a shopping mall. His fantasy was that the woman would say, "You don't need a gun. You're just what I've been waiting for," and then "rape" him. He kidnapped the women, tied them up, forced them to submit to intercourse, and then questioned them as to whether he was as good as other sex partners they had had. Mr. C had no criminal history other than the sex offenses. His background was unremarkable, but he had never felt that he did particularly well in any area of his life (academic, social, vocational, marital) with the exception of his military service. He dated actively as a teenager and indulged in pregenital sexual play, stopping short of intercourse. He found intercourse unsatisfying, partly because of premature ejaculation and partly because it never lived up to his expectations, although he could not define what was missing. He saw marriage as a solution, but since he could not be sensitive or attentive to anyone else's needs but his own, his marriage floundered. Mr. C discovered he was sterile and began having disturbing homosexual thoughts before his offense. He described the offense as a compulsion—something he felt he must do. Although he realized the consequences of what he was doing, he could not control himself. The six assaults occurred within a 2-month period.

Ms. D, a 21-year-old single woman, had just stepped off a bus on her way home from work and was walking in a well-lighted area of the city. A man approached her from behind, put a knife to her back, pushed her into some bushes, and pulled her sweater over her head so that she would not see him. He raped her vaginally and kept asking her questions such as: "How does it feel? Am I as good as your boy friend?" She said, "He seemed as if he needed to be reassured and so I tried to reassure him. I was lying on my back in the gravel . . . he was odd saying those things . . . then I had to bargain with him to get my clothes back. He also wanted my address and to know if he could come and do it again. I felt if I could convince him I was being honest, he would let me go. He had my pocketbook and would know who I was so I told him where I lived but not the right apartment." The medical record indicated abrasions on lower and upper back, with no other signs of bleeding or trauma.

Anger rape. In this type of sexual assault, the offender expresses anger, rage, contempt, and hatred for his victim by beating her, sexually assaulting her, and forcing her to perform or submit to additional degrading acts. He uses more force than would be necessary simply to subdue his victim. The assault is one of physical violence to all parts of the body: the rapist often approaches his victim by striking and beating her, tears her clothing, and uses profane and abusive language.

The aim of this type of rapist is to vent his rage on his victim and to retaliate for perceived wrongs or rejections he has suffered at the hands of women. Sex becomes a weapon, and rape is the means by which he can use this weapon to hurt and degrade his victim.

This offender displays a great deal of anger and contempt toward women. He sees them as unloving, ungiving "whores and bitches." Sex itself is regarded at some level as base and degrading, and the anger rapist typically finds little or no sexual satisfaction in the rape. He tends to react subjectively to the sexual act with revulsion and disgust, and he may experience difficulty achieving erection or ejaculation during the assault (22).

His relationships to important women in his life are fraught with conflict, irritation, and irrational jealousy, and he is often physically assaultive toward them. His sexual offenses tend to be episodic and sporadic, triggered by conflicts in his relationships to these women (mother, girlfriend, wife), but the anger is often displaced onto other individuals.

The rape experience for this offender is one of conscious anger or sadistic excitement. His intent is to hurt his victim, and his assault is brutal and violent. The motive is revenge and punishment; in extreme cases, homicide may result.

He finds it difficult to explain his assault when he cannot deny it except to rationalize that he was drunk or on drugs. Often the details are lost to his memory because he becomes "blind with rage" during the assault. Satisfaction and relief result from the discharge

of anger rather than from sexual gratification. He derives his pleasure from degrading and humiliating his victim.

Older or elderly women are a particular target victim for this type of rapist, although victims may be of any age. Medical examination generally reveals considerable physical trauma to all areas of the victim's body, often requiring X rays and consultation from other medical specialties. Victims report experiencing the rape as life-threatening, and their symptoms after the rape are disruptive to physical, behavioral, social, and sexual lifestyles.

Victims describe a blitz style of attack (20) or a sudden and dramatic switch in the offender's behavior. Having used a confidence ploy to entrap his victim, the offender then exhibits a behavior change in which he assaults her in a fury of anger. Victims may be physically immobilized and unable to use any coping strategies during the rape (24). Abusive and humiliating language may be used, and "perverted" acts are often a major aspect of the assault.

Rapists who fall into the anger-assault category can be subdivided into two groups on the basis of whether or not the degradation of the victim represents conscious rage or pleasure on the part of the offender.

The *anger-retaliation rapist* commits rape as an expression of his hostility and rage towards women. His motive is revenge and his aim is degradation and humiliation.

Mr. E is a 25-year-old married man and father of four. His mother abandoned the family shortly after his birth, and throughout his life his father reminded him that his mother was a "whore and never trust any woman; they are no good." During his adolescence he became acquainted with his mother and once when she was drunk she exposed herself to him and asked him to fondle her. He fled, terrified. In vain efforts to win his father's recognition and approval, he put a premium on physical toughness. In high school he played sports "like a savage." He then entered the Marine Corps and had an outstanding service record. After his discharge he married (against his father's wishes) and attended college. One day he got into a dispute with his female history teacher over the merits of the Viet Nam war and felt she was ridiculing and humiliating him in front of the class. He stormed out of the room, very angry, thinking "women are dirty, rotten bastards" and went to a bar for a few drinks. On his way to his car he spotted a 40-year-old woman (whom he described as looking older) in the parking lot. He grabbed her by the throat and hit her in the mouth; then he ripped off her clothes and raped her. Before this offense, Mr. E's only criminal record consisted of arrests for gambling, loitering, and drunkenness.

Shortly after midnight, Ms. F, a 33-year-old mother of two, was in bed reading and waiting for her husband to return from work. A man known to the family for 10 years knocked at the door and the 14-year-old son let him in. He said he was leaving town the next day and wanted to say goodbye. Ms. F talked to him from the bedroom and wished him well on his trip. Suddenly the man ordered the boy to his room, grabbed Ms. F, and forced her to go outside to another building. He beat her far more than was necessary to subdue her, choked her, and sexually assaulted her. On follow-up, Ms. F reported considerable physical pain from the beatings. She had pain and swelling of the face, neck, arms, and leg, and she reported loss of appetite, insomnia, nightmares, crying spells, restlessness, and a fear of being followed as she walked home from work. She was unable to carry out usual parenting and household tasks for the first week following the assault. There was tension within the marital relationship, delay in resuming sexual relations, and flashbacks to the assault.

The *anger-excitation rapist* finds pleasure, thrills, and excitation in the suffering of his victim. He is sadistic and his aim is to punish, hurt, and torture his victim. His aggression is eroticized.

Mr. G is a 30-year-old divorced man charged with first-degree murder. His victim, a 20-year-old woman he picked up at a singles bar, was tied to a tree, whipped, raped, sodomized, and slashed to death. Although found to be sane, he claimed he was high on drugs and could not remember what had happened. He had a criminal record that included assault and battery, breaking and entering, nonsupport, and motor vehicle violations. At the age of 17 he had tied a 13-year-old neighbor girl to a bed and assaulted her. He beat his children and burned his wife with cigarettes during intercourse. Shortly after his conviction, Mr. G committed suicide.

Ms. H, a 33-year-old single woman, was returning to her apartment at about 9:00 p.m. when she was suddenly jumped from behind and knocked to the ground. She remembered nothing until she awoke in the assailant's apartment. She was held captive there for 2 days, during which time she reported being continually beaten, raped, and forced to perform fellatio. She said, "He bit me and burned me. He had pictures of rattlesnakes on his wall." The medical exam revealed multiple injuries to her face and eye, multiple bruises and lacerations to her body, and human bite marks and cigarette burns on her chest. Ms. H was hospitalized for several days.

Rape, then, rather than being an expression of sexual desire, in fact is the use of sexuality to express issues of power and anger. In every case of rape all three factors coexist but their relative intensities and interrelationships vary. The incidence of each type of rape assault in our respective samples is presented in table 1.

Overall, power rapes outnumber anger rapes: of the 225 offenses studied, 146 (64.9%) were classified as power rapes and 79 (35.1%) as anger rapes. The anger-retaliation assault was the most frequent type of offense in the offender sample, but it ranked only third in the victim sample. One possible explanation is that the incidence of anger-retaliation rape is in fact lower than the incidence of power offenses, but since the physical evidence of anger assault is more apparent, the likelihood of conviction is greater. Consequently the anger-retaliation rapist may be overrepresented in the convicted-offender sample. The anger-excitation offender seems to be the least prevalent type among both samples.

TABLE 1
Incidence of Sexual Assaults Classified According to Typology

Type of Assault	Sample					
	Offender (N=133)*		Victim (N=92)**		Total (N=225)	
	Number	Percent	Number	Percent	Number	Percent
Power						
Assertive	50	37.59	48	52.17	98	43.55
Reassurance	22	16.54	26	28.26	48	21.33
Anger						
Retaliation	53	39.84	14	15.21	67	29.77
Excitement	8	6.01	4	4.34	12	5.33

*For those convicted offenders who also had a codefendant (N=21) each rapist is categorized separately.
**For those victims confronted with more than one assailant (N=33), the rape is categorized for the initial assailant.

DISCUSSION

The proposed conceptualization of the issues of power, anger, and sexuality in rape has several implications. Clinical work with offenders and victims indicates that the initial impact of rape is not sexual for either group. Although the act is sexual, what is traumatizing to the victim is the life-threatening nature of the assault, her helplessness and loss of control in the situation, and her experience of herself as the object of her assailant's rage. This is important because the etiology of the victim's trauma is the offender's pathology. Rape is more than an illegal act and more than an extreme of cultural role behavior. From a clinical point of view, it is important that rape be defined as a sexual deviation and that the pathology of the offender be recognized.

The clinical typology of offenders we have presented offers one approach to differentiating offenders with regard to identification, disposition, treatment planning, and prognosis. Further research is warranted to determine whether the trauma reaction varies according to the motivation of the rapist and to ascertain whether conviction rates differ for the four types of offenders.

Problems for Women in Psychiatric Residency

BY ELISSA P. BENEDEK, M.D., GAIL BARTON, M.D., AND CHRISTINE BIENIEK, M.D.

Some of the basic problems confronting women in psychiatric training are reflected in four major areas: supervision, administration, research, and peer relationships. The authors recommend a residency seminar on female psychology, flexible-schedule residencies, inclusion of more women in all phases of the profession, reeducation in female psychology for supervisors, more research opportunities, the availability of male and female mentors, and training program encouragement of peer support; these suggestions would help overcome the problems and improve training programs for women and men.

WOMEN PSYCHIATRIC residents encounter special problems in the areas of supervision, administration, research, and peer relationships. The similarity and intensity of the problems have stimulated this commentary, which highlights and describes common difficulties of women supervisors and trainees in psychiatry. We hope this paper will foster greater understanding and remedial action toward constructive change.

The literature, like the social setting in the United States today, emphasizes the differences between men and women entering medicine. For example, Cartwright (1) says that women are motivated toward medicine because of a desire for individuation; yet they share with men the additional motivations of encouragement by others and personal life-long interest in science. Nadelson and Notman (2) note that this motivation for individuation becomes blunted at the point of specialty choice, since women weigh this motivation against a "desire to feel accepted and needed rather than to continue to fight for recognition in a specialty such as surgery, where hostility to women is considered great."

Macoby, Jacklin, Hoffman, and others (3–5) report that women are more affiliative by nature than men. We concur and suggest that because of this characteristic, women tend to gravitate toward psychiatry. It is seen as a people-oriented rather than a technique-oriented specialty, and trainees expect affiliative needs to be met by peers, teachers, and supervisors, as well as patients. Unfortunately, this supposed people-oriented specialty seems unable to recognize that flexibility in role definement, didactic course content, supervision, and assignment would allow women to function simultaneously as psychiatric trainees, women, wives, and mothers (6). Therefore, the need for affiliation that initially drew women into psychiatry is largely unmet during training.

We suggest that although these problems exist, they are not inherent in residency training and are not insoluble. Awareness of such difficulties and concrete attempts to solve them would enrich the professional and personal lives of male and female psychiatric trainees, supervisors, and patients.

SUPERVISION

Supervision forms the core of psychiatric training and provides the trainee the opportunity to learn by identification, modeling, and education. The paucity of female supervisors available to trainees is undisputed (7). Moreover, both male and female supervisors tend to neglect important issues related to femaleness that arise between resident and patient and resident and supervisor. This discussion will be limited to those issues which arise between female residents and supervisors of both sexes. It serves only to illustrate a few problem areas and does not purport to be an extensive discussion of supervisory issues.

Unrecognized and unresolved conflicts between female resident and female supervisor may include problems about the handling of gender identity, as well as aggression and sexuality, between therapist and patient and therapist and supervisor. Preoccupation with the patients' dress, hairstyle, and other externals may overshadow concern about the true problems and roles of a particular patient, especially when these problems deal with the changing roles of women. For example, some senior female supervisors still encourage trainees to regard as normal in female patients the absence of a desire for home, husband, and children and the presence of an interest in career, education, and profession which may reflect their own orientation being imposed on the patient and the supervisor. Issues involving homoerotic transference and countertransference are often unrecognized or recognized and ignored because neither partner in the supervisory

The authors wish to thank Carol Wolman, M.D., and Anne Seiden, M.D., for their assistance.

dyad wishes to explore these issues; neither of them may have completely resolved these issues as yet. This is in marked contrast to the ease with which supervisors explore heterosexual transference and countertransference (8). In addition to disagreements about patient care, the relationship between a female supervisor and trainee may involve competition; the supervisor may see the trainee as a daughter who will achieve educationally and professionally what the supervisor is perhaps too old to do.

Problems with male supervisors may be similar or different. Male supervisors tend to view the woman trainee as a stereotypic female, that is, either warmly nurturant and passive or cold and castrating. For example, one young female trainee was rebuked by her young male supervisor for not being as warmly outgoing as his mother was. Another rather assertive woman resident was confronted by a generally passive and insecure male supervisor about her "castrating behavior" toward him. When such a stereotype is projected upon her, a woman's individual personality characteristics can be under-recognized, making a real and unique relationship difficult. Simultaneously and paradoxically, supervisors often seem bent on creating another stereotypic resident, one who is aggressive, strong, and dedicated to psychiatry to the exclusion of other important interests.

The male supervisor may often feel and act either overtly or covertly seductive with the female trainee. It is the rare supervisor who can reflect and handle his feelings appropriately if they emerge in supervision. Trainees comment on supervisors' patting them, holding their hand, asking them out, and behaving in even more flagrantly seductive ways. When confronted with problems of this sort, trainees are often reluctant to turn to other supervisors or colleagues for help, perhaps partly out of fear that they will be accused of somehow "inviting" such behavior. This situation is somewhat analogous to the manner in which rape victims in our society have been held responsible for encouraging their attackers.

Male and female supervisors frequently block the assignment of adolescent male patients to female trainees. Although no such restrictions are imposed on male residents treating female adolescents, some supervisors reason that the female trainee will be unable to deal with the sexual fantasies aroused in her patients and that acting out will be stimulated by the transference. One young female trainee was told by her experienced supervisor, an older woman, that she would not be able to treat adolescent males "until your hair is as white as mine." Female trainees can thus be denied the experience of treating male adolescents in a supervised situation. It is unusual for a supervisor to perceive the relationship of a female resident with a male patient as potentially constructive and therapeutic. One trainee reported that although she had announced her intentions of training in child and adolescent psychiatry early in her residency, it was impossible for her to have an experience on the adolescent ward. There were other female trainees in the department at that time, and the supervisor in charge of the adolescent ward flatly refused to allow more than one female trainee on the ward at a time. He felt that more than one female resident would "excite the boys."

Supervisors often are extremely solicitous and overprotective of women trainees, thereby excluding them from consideration for committee work, team leadership, or teaching opportunities with students from different health disciplines. One trainee reported perplexedly that although the department was short of resident staff to teach medical students, no one asked her to assume such a role. When she volunteered, she was confronted with "Are you sure you can do it?"

Typecasting of women residents as housewives and mothers is so strong that frequently when a woman resident is pregnant she is urged to discontinue her residency to care for her unborn child. One supervisor took a pregnant trainee to view a movie concerned with the effects of maternal deprivation on children. The trainee's own ideas about child rearing and career planning were not solicited, and her expressed wishes to discuss the issues openly were ignored. Ironically, when another woman trainee asked for a leave of absence to be with her children during their summer break, her request was denied. Individuation, both in completing a residency and supervising one, seems far in the future.

It is the exceptional supervisor who can discuss femaleness in supervision. When he/she can focus on such topics as pregnancy, menstruation, women in careers, divorce, courtship, and parenting, it adds a rewarding dimension (and from the woman's vantage point an *essential* one) that enables the resident to learn adequately about relationships with patients, families, staff, and colleagues.

ADMINISTRATION

Sexual role stereotyping also confronts women residents who desire training in administration. They are often invited to do the committee work associated with social occasions, decorating, or libraries but seldom are they considered appropriate candidates for chief resident, membership on a policy committee or on a committee to study program curriculum changes, or specialized course work in management.

The lack of a female role model among psychiatric administrators is very disheartening to the would-be administrative trainee. The female administrator needs female role models to most appropriately learn how to lead or to be heard in a meeting; how to create a leader-follower relationship, female to male and female to female; and how to handle the nuances of collegial relationships, female to male and female to female.

The feeling that one must learn these techniques and be, in a sense, an activist minority spokesperson may be eased somewhat when admission policies to medical school become more equalized and when con-

sciousness-raising experiences enable more men to accept women in leadership roles outside the home. Because of challenges to authority in general, female administrators have to struggle all the harder to survive. Role models of women in administrative posts exist if women are willing to look at the other health professions, especially nursing and social work. However, even in these predominantly female fields, the top posts quite often have been given to men. In addition to the heavy responsibilities of the administrative position, a female administrator-doctor faces a constant barrage of unacceptance or disbelief when she contacts others professionally for the first time (i.e., secretaries, ticket agents, lawyers, and other physicians).

Certain biases against a female administrator-psychiatric trainee will not likely pass without a period of consciousness raising. For example, supervisors assign women trainees to the less desirable posts, where prestige will be less likely to evolve. Women trainees are almost always questioned about the quality of their work and whether the responsibility being assigned is too much, whereas the competency of men in comparable posts is rarely doubted. The years of experience a candidate brings to an administrative position are usually taken into account when a man is assigned a task, but the woman administrator-trainee soon learns she must actively remind people that she is responsible, well trained, competent, interested, and available.

If women are going to project an image of competency, they will have to learn early in their training as administrators to speak up concisely (not to fumble with microphones but to handle them with aplomb), as well as to manage the financial and business aspects of administration.

These techniques of the administrator are usually conveyed in an informal, father-son relationship from one generation of administrators to the next. Until there are enough women in administration to make mother-daughter dyads of role modeling possible, the nourishing of a female administrative-trainee will have to be done by concerned, dedicated male administrators. These men will have to be willing to take the jibes of their fellow administrators, who will frequently allude to the sexual implications of the relationship. The administrator-mentors must become more aware that most male administrators are quite often quite intolerant of "this *woman* who thinks she's the boss." Both male and female trainees need to be aware that this may happen so that the male trainee will be less likely to feel so put out if his superior is a woman and so that the female trainee can be forewarned that she may be challenged. Frequently, disagreements develop when the female administrator-trainee tries to assert her role in the hierarchy only to be confronted with extreme hostility, resentment, and cries of unfair treatment by male peers. Too often the resulting clashes are passed over by the mentors as a woman's "bad days," "hysteria," or "sibling rivalry." They do not give opportunity for discussion, consciousness raising, or resolution of the problem because they lack understanding of the real issue—the conflict between a woman in an administrative role and a male peer with no experience or training in this type of relationship.

RESEARCH

The woman trainee in psychiatric research also finds that sex role stereotyping puts her at odds. She is perceived as much more capable of the clinical role, which is seen as nurturing, than the research role, which is more scientific, logical, competitive, and aggressive. The relative paucity of distinguished women researchers as role models in this field is alarming until one looks at the adverse conditions for training a woman in the field. Because there are relatively few research-oriented residency programs, geographic incompatibility may arise for women wishing to pursue this type of career.

Women may also have particular difficulties in finding a research mentor. Most psychiatrists (and other scientists) who go on to make significant research contributions have had, early in their research development, a close relationship with a senior research mentor who encourages, stimulates, and constructively criticizes and who may suggest research areas or offer collaboration in his or her own work. If both are male, this relationship often takes on a close father-son quality. There is considerable intellectual and personal excitement in developing and discussing ideas—and later, often some ambivalence in the growth phase of "challenging the old man" (7). These relationships also have rich and interesting transference-countertransference aspects (whether they are ever explicitly discussed or not).

However, when the younger researcher is female and the older one is male, there may be special complications. If a father-daughter relationship exists between a male senior researcher and a female resident, the intimacy of sharing gestating ideas can frequently have erotic overtones for either or both of them. Moreover, if the mentor is middle-aged, he may be involved in a mid-life crisis of his own, which, in our society, is frequently handled by seeking overt sexual relationships with a younger woman. This can increase the tension related to the resident-mentor relationship.

If the female resident finds a woman mentor, this relationship, too, has its problems. Traditionally, mothers in our society have taught daughters to limit their aspirations for individual accomplishments, warning them of the pitfalls and hardships ahead and teaching them how to find trustworthy men on whom to lean. Although these may be adaptive strategies in social life, they are not research attitudes. A woman mentor may not be able to adequately prepare the female resident for special difficulties in getting faculty positions and research grants. More dynamically, she may have her own difficulties in these areas (e.g., the

use of denial) so that she either cannot help the younger woman with the same problems or finds her own denial threatened painfully. A special kind of envy may develop if a woman resident can resolve conflicts with male colleagues without passively submitting. Occasionally, one may find an older female mentor encouraging her student to act out her conflicts with male colleagues—conflicts that the mentor was forced to deny. Despite these difficulties, however, many young women have been very effectively encouraged by mentors of both sexes.

The woman resident, as a consumer of research, finds that many of the authorities cited in literature seriously question whether she has the ability to understand them and join them as colleagues. They describe women as narcissistic, having a weaker superego, more passive, or more masochistic. These negative descriptions are not likely to stimulate her to delve more deeply into psychiatric literature or to pursue role modeling toward that type of research.

PEER RELATIONSHIPS

The female resident frequently finds herself alone in her peer group, facing all the very real problems mentioned in the literature by Wolman (9). In a training center athletics is a traditional outlet for social interaction among resident-resident, resident-senior staff, and senior staff-senior staff. However, the woman resident is usually given the clear message that it is for men only—women are not sports participants anyway. The recent upsurge in interest in tennis has changed this attitude slightly, but it is still strong in regard to paddleball, softball, and skiing. Study groups among peers tend to be segregated sexwise also, excluding the solitary woman resident. Should the woman trainee try to participate in the sessions, the kidding and innuendos that go on highlight the awkwardness and cancel the advantages of group study. The tendency to nominate the other "guys" for committee and prestige positions and to ask women to plan social events in the residency program further isolates the women trainees; recognition of the woman trainee's individual skills is still buried in sex stereotyping.

This solitariness and lack of peer support poses a more critical problem for women than for men when one considers the importance of affiliative need in female development. The professional woman alone in a peer group has no one with whom to build affiliative bonds. If she is, as Hoffman (4) postulates, developmentally more affiliative than competitive, she finds some of her most basic psychological needs thwarted and unmet. Additionally, because sexual feelings are part of our daily lives and because residents are learning to deal with sexual transference, these feelings occur between male and female peers in training. Unfortunately, this can sometimes lead to acting out by both male and female residents. However, if residents avail themselves of the unique opportunities to more closely explore these feelings, it can lead to strong bonds of friendship.

Psychiatric residency training can be a lonely exploration of one's self if one is without a cohort or peers. The female resident who is alone in a group complains of feeling isolated, lonely, and depressed; while such feelings may be due to the stresses of the training program and/or interpersonal dynamics, often the training situation itself is such that the resident is alone or isolated.

RECOMMENDATIONS

We hope that highlighting the problems of women in psychiatric residency will stimulate improvement of training programs. Men in psychiatry will benefit from the improvements as well: suggestions for changing the residencies should create an atmosphere conducive to learning about both women and men.

We suggest the following actions to overcome the problems:

1. A seminar on female psychology should be part of the standard curriculum. It should involve surveying the existing literature, noting the lack of a researched data base and the obvious inconsistencies, so that some residents will be stimulated to enrich the field by researching female psychology.
2. Flexible-schedule residencies should be created, not just in a few geographic areas but nationwide. Then women could choose programs that are more realistic for them in regard to where they wish to locate permanently and to the amount of time they feel is important for child rearing. This flexibility should also allow men in medicine the opportunity to be more involved in child rearing, in contrast to earlier attitudes, where the father was expected to work long hours and sacrifice his and his family's emotional needs for those of his patients during his training or career.
3. More women should be admitted to medical schools, psychiatric residencies, supervisory positions, administrative posts, and research consortiums. Having women in such posts and training them for these positions will create an environment conducive to accepting women in these roles, providing role models for other women, and creating a cadre of women experts from which to learn.
4. In-service education is necessary for supervisors, administrators, and teachers in psychiatry to help them see that they do tend to view women stereotypically rather than individually. Most need to explore women's roles beyond those of wife and mother. They also should explore what roles men might play beyond that of provider, such as participating more in child rearing.
5. More specific data collection, research, and training around the whole aspect of supervision of psychiatric trainees is needed. All too often a person becomes a supervisor simply because he/she is in the care-delivery system and not because he/she is partic-

ularly skilled at teaching or has specific skills or knowledge. Supervisors should have as part of their usual armamentarium a thorough grounding in female psychology. They should be willing to discuss this with their male and female trainees and to work through any male and female transference and countertransference issues that might develop in the course of supervision.

6. More specific attention should be given to training women psychiatric administrators so that they learn requisite business, financial, and technological skills as well as clinical skills.

7. All training centers for psychiatry should have research available as part of the training program so that geography is not a barrier to a potential researcher. Otherwise, women, who tend not to move themselves and/or their families to the few areas where research opportunities are currently available, become excluded from contributing to research.

8. Research trainees should have both male and female mentors available. Affirmative action may be necessary to implement this. Since there is an underrepresentation of women in this area and too few role models, research centers will have to be more willing to encourage female trainees into more research-oriented roles.

9. Training programs may well want to pay more attention to providing peer support. Residency-staff social, athletic, and study get-togethers should not be left to chance. Peer support means the difference in camaraderie, a sense of belonging for all trainees, an esprit de corps for the institution, and the building of lasting friendships and professional relationships.

Phenytoin Treatment of the Binge-Eating Syndrome

BY BRUCE M. WERMUTH, M.D., KENNETH L. DAVIS, M.D., LEO E. HOLLISTER, M.D., AND ALBERT J. STUNKARD, M.D.

Nineteen subjects completed a 12-week double-blind crossover study comparing phenytoin with placebo in the treatment of severe binge eating. In the placebo-phenytoin sequence the number of binges decreased during phenytoin treatment from both placebo and pretreatment levels. However, in the phenytoin-placebo sequence, not only did phenytoin reduce the number of binges from pretreatment levels, but there was no reversal of this effect during the placebo period. This sequential effect was unexpected and is still unexplained. The mechanism of phenytoin action and the significance of EEG abnormalities found in 7 of the subjects remain uncertain.

THIS STUDY was stimulated by a report on the effectiveness of phenytoin (diphenylhydantoin, Dilantin) in treating 9 of 10 persons with "compulsive eating" problems (1). The purposes of this study were to gain a clearer understanding of the clinical syndrome of binge eating and to test the efficacy of phenytoin treatment in a controlled clinical trial.

METHOD

Subjects

The criteria for the diagnosis of binge eating were as follows:

1. Impulsive, unpredictable, episodic, uncontrolled, and rapid ingestion of large quantities of food over a relatively short period of time.
2. Termination of the episode only when a point of physical discomfort has been reached (e.g., abdominal pain, and feelings of nausea or distention). Self-induced vomiting supported but was not required for the diagnosis.
3. Subsequent feelings of guilt, remorse, or self-contempt.

A frequency of at least one binge per week with no binge-free intervals of longer than three weeks during the previous year was also required for inclusion of subjects in the study.

Twenty subjects were recruited from the following three sources: 1 from the Stanford Student Health Service, 4 from the Stanford Eating Disorders Clinic, and 15 from newspaper advertisements. Since binge eating has been described only occasionally and the frequency of its occurrence has never been estimated, we will briefly describe our selection procedure to provide a first such estimate. The subject from the student health service was the only person known to have complained of binge eating out of approximately 600 men and women of college age seen during a 5-month recruiting period. The four binge eaters from the eating disorders clinic were drawn from the files of approximately 200 persons, primarily obese, who had been seen over the preceding 2 years. The newspaper advertisement ran for 11 consecutive days in the San Jose *Mercury* (circulation 207,000) and the Palo Alto *Times* (circulation 44,000). There were 242 telephone inquiries from this ad, of which 201 were screened out; 152 subjects did not meet the diagnostic criteria and 49 had only rare episodes of binge eating. Of the 41 persons who were personally interviewed, 26 were screened out. Fifteen were eliminated because the frequency of binge eating was less than demanded by our criteria and 11 for other reasons, primarily insufficient interest. Fifteen of the subjects answering the advertisement met all of the criteria for inclusion in the study and entered treatment.

Careful medical and psychiatric evaluations were carried out by two psychiatrists who ascertained the suitability of subjects for the study. The nature of the study was fully explained to the subjects prior to obtaining their informed consent. Because of earlier reports of EEG abnormalities in binge eaters, each subject received a waking and sleep EEG with nasopharyngeal leads (1–3). Initial laboratory tests included a complete blood count and a chemical screening battery (SMA-12).

All of the subjects were women, and they had a median age of 26 years (range, 17–42), as shown in table 1. Using the Metropolitan Life Insurance Company's

height-weight tables, we found that 10 subjects were of normal weight, 4 were overweight (10–20% overweight), 5 were obese (more than 20% overweight), and 1 had active anorexia nervosa (20% underweight). Two subjects had a past history of anorexia nervosa, and 2 (including the active anorexic subject) reported problems with alcohol. Other than these difficulties, the subjects were in good physical health, worked or attended school, and showed no evidence of emotional disturbances except that associated with their eating binges.

The onset of the eating binges occurred at a median age of 16 years (range, 9–26), with a median duration of 11 years (range, 2–24) and infrequent binge-free intervals. The median frequency of the binges at the onset of treatment was 3–4 per week (range, 1–7). Most subjects had undergone many treatments for their binge eating, including diets, medications, hypnosis, and commercial or self-help weight control programs. Seven had been in psychotherapy. No treatment had been successful. Descriptive data about the subjects are presented in table 1.

Procedure

Active medication and placebo were administered for 2 6-week periods, each according to a double-blind crossover design. One 6-week period involved treatment with a placebo, the other with active medication. Subjects were randomly assigned to each protocol. Thus there were 2 treatment groups: a phenytoin-placebo sequence and a placebo-phenytoin sequence. Medications were prepared in sets of 6 bottles for each subject, each bottle covering a 2-week treatment interval. All bottles and capsules looked alike. The initial dosage was 1 capsule of 100 mg of phenytoin or placebo 3 times a day.

The subjects were seen weekly by a psychiatrist who did not know which medication they were taking. Each week the psychiatrist reviewed with the subjects the individual forms that they had completed at the time of each binge. The forms included a rating of the intensity of the binge as recorded on a 10-cm visual analogue scale. The psychiatrist weighed each subject, noted any changes in mood, behavior, and eating patterns, and checked for any sign of adverse drug reaction. At no time were instructions in dieting or weight control given, nor was there any psychotherapy.

Serum phenytoin levels and routine hematological studies (complete blood count and liver function tests) were obtained every 2 weeks and the results monitored by another member of the research team. This medical monitor attempted to keep the phenytoin levels in the range of 10–20 μg/ml by requesting appropriate changes in dose. Similar dosage changes were ordered during the placebo period to keep the treating psychiatrist as uninformed as possible.

RESULTS

Nineteen of the 20 subjects completed the study. One subject (number 20) developed a generalized urticarial reaction to phenytoin and had to be withdrawn from the study. Twelve subjects achieved final serum phenytoin levels of 10–20 μg/ml and 5, levels of 5–10 μg/ml. Two subjects (numbers 9 and 19) had phenytoin levels consistently below 3 μg/ml, which raised the possibility of noncompliance. Their data were included in the analysis since they completed the study before the situation was corrected.

The data were first analyzed by comparing the mean number of binges per week estimated by subjects (historical control) and those during both experimental periods (see table 2). In the phenytoin-placebo sequence, the mean number of binges per week was significantly decreased during phenytoin treatment to 2.4 ± 1.9, compared with the historical control of 3.8 ± 1.4 ($t=3.66$, $p<.01$). However, when these subjects then changed to placebo, their improvement continued so that no significant difference was found between the phenytoin and placebo treatment periods. In the placebo-phenytoin sequence, the mean number of binges

TABLE 2
Results of Treatment with Phenytoin and Placebo

Sequence and Subject	Estimated Binges per Week	Binges per Week	Binges per Week	Clinical Degree of Change

18	3.5	5.3	4.2	Slight
19	5.5	3.7	2.0	Slight

per week during the placebo period (3.6±1.9) was not significantly different from the historical control (3.7±1.8); however, there was a significant decrease during the phenytoin treatment to 2.2±2.0 ($t=3.98$, $p<.01$). Differences between the phenytoin-placebo sequence were compared with the placebo-phenytoin sequence. The former sequence showed significantly fewer binges ($t=2.64$, $p<.02$) than the latter, indicating that an unexpected carryover effect was present in that sequence.

Individual data were assessed by comparing the number of binges during phenytoin treatment with that of the control period. For the placebo-phenytoin subjects the placebo period served as the control, while for the phenytoin-placebo subjects the pretreatment estimate of binge-eating frequency was used because of the carry-over contamination effect of the placebo period. If the number of binges was reduced by 75% or more during phenytoin treatment, the subject was considered to be markedly improved; reduction of 50% to 74% was considered moderate improvement; reduction of 20 to 49%, slight improvement; reduction of less than 20%, no change; and an increase of 20% or more was considered to represent worsening.

As can be seen in table 2, 2 subjects in the phenytoin-placebo group were markedly improved on phenytoin, 2 were moderately improved, 3 were slightly improved, and 3 showed no improvement. In the placebo-phenytoin group 4 subjects showed marked improvement, 3 were slightly improved, and 2 showed no improvement.

Subjects whose binge eating was markedly reduced during treatment with phenytoin reported more self-control, a marked improvement in self-esteem, less preoccupation with eating, and movement toward more normal eating habits.

There were no consistent changes in weight or intensity of binges during the study.

Definitely abnormal EEGs were seen in only 3 subjects (table 1). In 4 others "small sharp spikes" were noted; this is a controversial pattern of questionable significance (4, 5). Excluding one patient who had a definite EEG abnormality and was withdrawn from the study, the remaining 6 subjects with abnormal EEGs had the following clinical responses: 1 showed no improvement, 2 showed slight improvement, 1 showed moderate improvement, and 2 showed marked improvement. These improvements were similar to those experienced by subjects without EEG abnormalities, and thus EEG abnormalities were not correlated with treatment response. Since the EEGs were not obtained close to the time of an actual binge episode, these abnormalities may be unrelated, or we may have found normal EEGs in subjects who might have shown abnormalities on other occasions.

We examined the clinical and experimental data for variables that would predict favorable or unfavorable treatment response. Only two items seemed to predict outcome: length of binges and history or presence of anorexia nervosa. Short duration of binges (one hour or less) was uniformly associated with a good response. A history of anorexia nervosa was associated with no improvement in both cases, as was similarly found in a recent single case report (6). The following items did not predict treatment outcome: EEG findings, phenytoin blood levels, weight, frequency of binges, night eating, frequent snacking, eating continuously during the day, eating at regular mealtimes, and postbinge emesis.

DISCUSSION

The report that stimulated this study was an uncontrolled trial of phenytoin with what was called "compulsive eating" (1, 3). Our study was a controlled clinical trial of the effects of phenytoin on what we prefer to call "binge eating," a more descriptive term for what we believe to be the same syndrome. The reasons for this preference have been described elsewhere (7). A brief description of the syndrome follows.

The binge-eating syndrome consists of episodic, uncontrollable, rapid ingestion of large quantities of food over relatively short periods of time. It occurs while the person is alone and has an air of secretiveness. The food is usually consumed rapidly with little or no chewing. The foods eaten tend to be sweet and starchy

items that lend themselves to rapid consumption. Often there is little preparation of the foods and they are eaten directly from their containers, often without the usual preparation such as thawing or heating. As the episode of binge eating progresses, there is decreased selectivity of food items, and unusual food combinations or foods not generally enjoyed are then consumed. If food runs out before the binge terminates, the person will seek out additional food. The binge usually lasts 1–2 hours but can be as brief as 20 minutes or as long as an entire day. The binge is terminated by severe abdominal discomfort, vomiting, or sleep. Social interruption usually temporizes a binge, which then continues when the intruder leaves.

Immediately after a binge, the person experiences strong self-contempt and guilt. There is a resolve not to binge eat again. A strict diet is begun. Normal eating patterns are rarely achieved and the person becomes preoccupied with food, occurrence of binges, weight control, and dieting. The onset is in adolescence or early adulthood, and the syndrome is more prevalent among females than males. There may or may not be an associated weight problem, depending upon the degree of regurgitation immediately after a binge and the success of dieting between episodes. With many individuals the course appears unrelenting and unresponsive to a wide variety of therapies. These findings support an earlier contention that binge eating is a distinctive type of eating pattern abnormality (7, 8).

Our study intentionally selected persons with frequent binges, omitting a larger number with less frequent binges; thus milder forms of the syndrome were excluded. Judging from the large number of these milder cases and the relative ease with which we located our subjects, the syndrome is probably not rare. The very secretiveness and guilt surrounding it may prevent more binge eaters from identifying themselves.

The efficacy of phenytoin as a treatment was considerably less in this study than in an earlier one in which 90% of the subjects returned to normal eating (1). This discrepancy could have resulted from the inclusion of more seriously afflicted subjects, the elimination of placebo response, and the shorter duration of treatment employed in our study.

Our results were further confounded by the effect of treatment sequence, in which there was an unexpected persistence of treatment effect in the placebo period for the subjects in the phenytoin-placebo sequence. The action of phenytoin terminates soon after it is discontinued, and during periods of placebo treatment, virtually all subjects had no detectable plasma concentrations of phenytoin. Thus a prolonged drug effect is most unlikely. When the data from the placebo phase of the phenytoin-placebo sequence were examined at successive 2-week intervals, we detected no progressive increase in frequency of binges over time, which sustains the impression that a residual, but slowly disappearing drug effect was not present. One may speculate that a learning effect is created once the pattern of binge eating is interrupted. In any case, this sequence effect will have to be considered in planning any future controlled trials of drugs in this disorder.

Two recent reports are relevant to the present findings. One report (9) described the response of transvestite behavior of 20 years' duration in a 38-year-old man to small doses of phenytoin. As in the current study, there was no recurrence of problematic behavior after discontinuation of medication. (The patient was followed for a 20-month period.) The second report (10) described the successful treatment of binge eating by purely behavioral measures. These two studies suggest that, whatever the initial mechanism of action of phenytoin in controlling binges, learning may play an important part in their continuing control.

Treatment did not result in consistent weight changes, which may be explained by the short duration of treatment, our lack of emphasis on weight loss, and the majority of normal-weight subjects. Our experience suggests that in the overweight and obese population, binge eating is an infrequent problem.

The etiology of this syndrome remains speculative. Its episodic, uncontrollable nature and occasional favorable response to phenytoin suggests a possible variant of psychomotor epilepsy. The few EEG abnormalities, while epileptiform in morphology, do not correlate with treatment response and are of unknown significance. A hypothalamic etiology has been proposed and is based largely on the interpretation of 14- and 6-per-second positive spikes as abnormal (1, 3). Most electroencephalographers, however, consider these spikes to be normal variants (11–13). The existing data are too inconclusive to support a claim of hypothalamic etiology, and other alternatives must be considered.

The mechanism of action of phenytoin in binge eating is unclear, but it resembles its anticonvulsant action, i.e., the frequency of binges but not their intensity is diminished. However, three other features suggest that at least conventional anticonvulsant activity did not account for the binge-reducing activity of the drug: the effectiveness of phenytoin in preventing binges at serum levels as low as 5 μg/ml, the small minority of persons with abnormal EEGs, and the lack of correlation between EEG abnormality and treatment outcome. This medication is reported to have a wide variety of properties, other than anticonvulsant action, that may play an important role, thus suggesting the usefulness of future comparisons between phenytoin and drugs with nonspecific sedative action (14, 15).

ADDENDUM

Since completion of the original study, all but 3 subjects who could not be located (patients 9, 11, and 19) were followed over the subsequent 18-month period. Their data provide the first longitudinal study of a group of binge eaters.

Only the 6 subjects who showed marked improvement during phenytoin treatment were given the option of continuing treatment on a supervised, open-trial basis. Four subjects elected to continue treatment, while 2 decided not to for personal reasons. Of the 4 subjects who continued treatment, 2 (patients 1 and 12) had no further episodes of binge eating. Two (patients 2 and 15) noted the return of their binge-eating pattern during the first 2 months and discontinued treatment. At the present time they continue to have binges at their estimated pretreatment frequency. The 2 subjects who did not elect to continue treatment (patients 13 and 16) also continue to have binges at their estimated pretreatment frequency.

Of the 14 subjects who were not treated during the follow-up period or who discontinued treatment during the first 2 months, there was a small tendency ($p<.05$, Mann-Whitney U Test) for binges to be less frequent than during the pretreatment period, but the meaning of this difference is not clear. Eleven subjects reported a decreased frequency of binges, 1 reported a slight increase, and 2 subjects showed no change. Much of this effect was contributed by 3 subjects who showed marked decreases in binge frequency. The number of binges per week for patient 14 decreased from 5.0 to 0 after a divorce, for patient 5 from 3.0 to 0.5 after a particularly meaningful encounter group experience, and for patient 2 from 4.0 to 1.0 for reasons that are not clear.

Did the carry-over effect persist after the end of the active study period, and did it contribute to the decreased binge frequency during the follow-up period? The answer to both questions is probably no. Consider first the 5 subjects in the phenytoin-placebo sequence who apparently showed the carry-over effect (patients 1, 4, 5, 8, and 9). The data on 2 subjects are noncontributory; patient 1 continued on phenytoin, and patient 9 was lost to follow-up. Two (patients 4 and 8) are binge eating at pretreatment levels, and the decreased binge frequency of patient 5 seems adequately explained by her encounter group experience. It is difficult to interpret the results from the placebo-phenytoin sequence. Three phenytoin responders (patients 13, 15, and 17) have returned to pretreatment rates of binge eating, while 2 responders (patients 16 and 18) have maintained lower rates.

From these follow-up data one might conclude that phenytoin continues to be highly efficacious in the treatment of a few selected binge eaters. For those subjects who did not initially respond to phenytoin or those who did not elect to continue phenytoin treatment, binge eating persisted; the few exceptions are perhaps attributable to psychological changes in the subjects' lives.

Psychiatric Disturbances Associated with Erhard Seminars Training: II. Additional Cases and Theoretical Considerations

BY MICHAEL A. KIRSCH, M.D., AND LEONARD L. GLASS, M.D.

In a previous article, the authors reported on 5 individuals who developed psychoses after participation in Erhard Seminars Training (est). Two additional cases are reported, and the combined case material is discussed in terms of group and psychodynamic theories. The authoritarian est leadership style may mobilize in trainees an overdetermined and pathological reliance on identification with the aggressor. Such a mechanism may be central to the production of psychiatric casualties, particularly in individuals with defective ego boundaries. Future controlled research is necessary to ascertain the rate of occurrence of psychiatric disturbances associated with est and to test the authors' hypotheses.

IN THE FIRST part of this report on psychological complications associated with Erhard Seminars Training (est) (1), we described 5 cases of psychosis temporally related to the training. A large, quasi-therapeutic group experience, est is becoming widely available in this country. The training occurs over two weekends, usually in hotel convention halls, in groups of 250 trainees who now pay $300 for the 60–70 hour experience. The trainer employs an authoritarian model, and trainees are not permitted to leave, talk, eat, or go to the bathroom during the marathon sessions except as dictated by the leader. The training consists of Gestalt-like exercises, didactic material, and scheduled self-disclosure, carried out in a forceful, confrontational style. A fuller description of the est training program appears in our earlier report (1).

The est organization does not advocate the training for people who have a history of psychiatric hospitalization. Applicants who are in psychotherapy but are dissatisfied or believe they have fared poorly in therapy in the 6 months before the course are also reportedly discouraged. If the prospective trainee chooses to disregard these recommendations, clearance from the therapist and the therapist's pledge of availability to the enrollee during and after the training is said to be required (2).

There is no formal follow-up procedure. Post-training contact by the est organization consists of telephone calls and mailings urging the graduate to return for continuing "postgraduate" seminars.

Our experience with the est program includes 7 cases of psychological distress temporally related to the training, 5 of which were included in our first report. This group of est trainees came to our attention through our work in a variety of emergency psychiatric settings. In addition, one of the authors of the first article (F.P.) personally completed the basic est training.

CASE REPORTS

Case 6. Ms. F, a 26-year-old single high school teacher, developed hyperphagia and an acute depression after the est training. The oldest of two children born to parents of Asian extraction, she has a master's degree in education and her brother has a bachelor's degree. Her father had a successful health food business and her mother increased the family fortune by investing wisely in the stock market. When Ms. F was 21, her mother died of gastrointestinal cancer. Ms. F had many friends while growing up and energetically involved herself in church activities during adolescence. She excelled in school. Neither she nor any member of her family has a prior psychiatric history.

When she was 24, a long-term involvement with a man floundered, and Ms. F enrolled in est in an effort to salvage the relationship. During the training, she recognized her pattern of being the "victim" in her relationships, a painful insight that shook her self-esteem. She could not "share" her discomfort with the group because she felt "the leader did not want to hear negative experiences," and "the group would not be supportive."

During the first weekend of the training, Ms. F began gorging and in the next month gained 30 pounds. After completing the training, she became "apathetic" and "lost interest" in life. She broke off contact with friends and moved back into her father's house. Her life became a drab routine of attending school and returning home to eat and sleep. She contemplated suicide intermittently (but made no attempts) and describes this period as "the worst time in my whole life." In an attempt to ameliorate her psychic distress, she took a postgraduate est course entitled "Be Here Now." This course intensified her depression and made her feel like

When this work was done, Dr. Kirsch was a Resident in Psychiatry, Langley Porter Neuropsychiatric Institute, University of California, San Francisco, where Dr. Glass was Director, Emergency Service. Dr. Kirsch is now in private practice at 2154 Broderick St., San Francisco, Calif. 94115, and Dr. Glass is Assistant Psychiatrist, McLean Hospital, 115 Mill St., Belmont, Mass. 02178, and Instructor in Psychiatry, Harvard Medical School. Address reprint requests to either author.

The authors wish to acknowledge the collaboration of Dr. Frederick N. Parris in the preparation of this work.

a "misfit" because she could not "get it."

Two months after the initial training and a total of 40 pounds heavier, she sought professional help and initiated twice-weekly psychotherapy. Five months into therapy, her depression began to clear, she began to lose weight, and she recontacted friends. Ms. F finished her master's degree and obtained work as a teacher. She is currently in uncovering psychotherapy twice weekly and continues her teaching career.

Case 7. Ms. G, a 24-year-old unemployed single woman, became confused, disoriented, and frightened immediately after the est training. This reaction improved spontaneously in a few days. Six months later during an est postgraduate seminar the patient developed delusional thinking.

Ms. G is the youngest daughter of an abusive alcoholic father; her mother, described as warm and loving, died when she was 11 years old and she was cared for by a series of foster parents until she was 18. Her two older siblings are both professionals. Although she was a poor student and a disciplinary problem, she graduated from high school. After graduation she worked intermittently as a cashier in a grocery store. Ms. G sporadically abused amphetamines while "dieting." She has no formal psychiatric history; her father was hospitalized several times for alcohol-related problems.

In the fall of 1975, after separating from a boyfriend, Ms. G enrolled in est to help her "communicate with people," "lose weight," and "pull out of a depression." On the last day of the second weekend of training, she became "confused" and was unable to locate her car without police assistance. Her confusion subsided in the next few days, but she felt inadequate and isolated herself from her friends. She did, however, reconcile with her boyfriend.

Five months later, Ms. G took the "Be Here Now" course. During the program, she felt "propagandized" and was bewildered by such statements by the trainer as "Let it be okay not to be something before you can be it." She stated that the concept, "talking in the back of my head," "blew my mind." During the training, her "thinking went wild" and she began "thinking about thinking." In the midst of the course she became delusional, thinking that she was the Virgin Mary, that the trainer loved her, and that Werner Erhard was inside her. Following the postgraduate est course, Ms. G became more isolated, her personal hygiene deteriorated, and she stopped doing housework.

Three months later she became preoccupied with est, isolated herself from her family, began staring into space, and heard voices. She had become convinced that Werner Erhard was inside her and that she was in communication with him. She was hospitalized at her community mental health center and treated with antipsychotic medication. During her 6-day stay, her behavior became more appropriate, but at the time of discharge, she continued to report occasional auditory hallucinations. Her discharge diagnosis was acute schizophrenic episode. She was referred for outpatient treatment with a recommendation that she continue taking haloperidol, 15 mg/day. Five months later she is able to work part-time, supported by antipsychotic medication and weekly psychotherapy.

RESULTS

Our population consists of the 5 cases reported in our previous article and the 2 presented above. Demographic characteristics and psychopathology are summarized in table 1. The average age is 30, and the group is nearly equally divided between men and women. Five individuals are Caucasian and two are of Oriental extraction, which is probably a reflection of the ethnic makeup of the San Francisco Bay area. Educational attainment of the group is above average, which is consistent with reports that est appeals to a more established, middle-class population than other popular psychological movements, which draw participants from the alienated subcultures.

Of the 6 patients who had clear psychotic episodes, only one had a history of psychosis. It is striking that the modal individual in our study was well educated and productive, with no history of treated psychiatric illness or hospitalization.

Five patients experienced schizophrenic episodes, 3 of the paranoid type and 2 of acute schizophrenia. The remaining cases were 1 first-break manic-depressive illness and 1 depressive neurosis. The severity of these difficulties is suggested by the diagnoses. The participants' subsequent courses (over a period of several months to 3 years) are consistent with those expectations. Only 1 patient has had no recurrence or evident impairment. The others have had marked constriction in life activities and/or relapses into psychotic states.

DISCUSSION

As we have stated previously, no determination can be made on the basis of our findings alone regarding the causation or frequency of associations between est and psychiatric morbidity. Nonetheless, we believe a discussion of possible etiologic mechanisms is warranted to aid clinical management and future systematic study. In this effort, consideration will be given to group and psychodynamic explanations.

Group Dynamics

The paucity of literature on complications of participation in large quasi-therapeutic groups necessitates a review of the relevant experience with encounter groups. Recognition of psychological injury to some participants of encounter groups led to the American Psychiatric Association task force report, *Encounter Groups and Psychiatry*. After outlining the shortcomings of research in this area, the task force concluded that

> no generalization may be made save that, in the hands of some leaders, the group experience can be dangerous for some participants. The more powerful the emotions evoked, the less clinically perspicacious and responsible the leader, the more psychologically troubled the group member, then the greater risk of adverse outcome. (3, p 17)

More recently, Lieberman and associates (4) wrote a book-length prospective study of encounter groups, including a case-by-case analysis of the 16 individuals

TABLE 1
Characteristics of Seven Patients Who Developed Psychoses After est Training

Case Number	Age	Marital Status	Education	Psychopathology	Course
1	39	Married	College	Acute schizophrenic episode	No recurrence
2	26	Single	College	Schizophrenia, paranoid type	Constriction
3	28	Married	Postgraduate	Acute schizophrenic episode	Constriction
4	34	Married	College	Manic-depressive illness	Recurrences
5	30	Single	College	Schizophrenia, paranoid type	Constriction
6	26	Single	College	Depressive neurosis	Constriction
7	24	Single	High school	Schizophrenia, paranoid type	Constriction

in a sample of 206 who suffered significant psychological injury. While conceding that their methods clearly underestimated the number of casualties, the authors stated that "a casualty rate approaching 10% is alarming and unacceptable in an endeavor calculated to foster positive growth."

It is reasonable to assume that some awareness of the possibility of similar injury to participants in est's large-group experience led the organization to adopt the screening procedures described earlier. However, in our small sample, 2 individuals failed to meet the stated est screening criteria (case 5, Mr. E; and after the first episode, case 4, Ms. D) and either were not detected or not acted upon. No contact was made with either treating psychiatrist and no authorization from the physician was required for further participation in the est program. Thus profoundly disturbed individuals may not be excluded by the est screening procedure.

The lack of emphasis on screening is consistent with est practice, which provides essentially the same training experience for each new group without consideration of the specific psychological needs of the individuals enrolled. Fenwick (5) has pointed out that sophisticated assessment of individual psychopathology is beyond the competence and training of the est personnel; it is also outside the est value system, since the training is held to be almost universally beneficial. Fenwick also believes that "est uses techniques indiscriminately which, in a certain proportion of the population, are known to be harmful and potentially quite dangerous."

The est organization does not follow its clients in a manner that would mitigate the deficiencies of the screening process or attempt to rectify whatever disruption might result from the training itself. Several of our patients commented that the only further attention they received after the course was pressure and inducements to enroll in additional est activities.

Clearly, much of the toxicity of any injurious group experience is determined by the approach and conduct of the leader.[1] Lieberman and associates (4) examined the contribution of the style of encounter group leaders to subsequent psychological injury of participants in the group they led and found that one leadership style was associated with a disproportionate number of the casualties and tended to produce the most severe injuries. These "Type A—Energizers" are intense emotional stimulators, most committed to an articulated belief-system and to the founder of their school of thought; they are highly charismatic, proselytizing, "religiostic," and intent on firmly directing participants toward "the road of salvation." Elsewhere, Yalom and Lieberman (6) have described these leaders as "aggressive stimulators—intrusive, confronting, challenging and authoritarian."

Although we did not observe the est trainers in the sessions our patients attended, information from our patients and other sources (5, 7) leaves little doubt that est leaders could be classed as Type A. This style so uniformly typifies the est trainers as to defy coincidence. Apparently this authoritarian, confrontational style is sought and developed to transmit the est message in an unmistakable and characteristic mode. However, this approach systematically replicates the leadership style with the greatest known capacity for

[1]Reference to the encounter group literature may be helpful in understanding specific mechanisms of psychological injury to group members. Lieberman and associates (4) have identified five factors that resulted in casualties to encounter group participants: attack by the leader, rejection by the leader, failure to attain unrealistic goals, coercive group expectations, and input overload. Descriptions of their experience of the est process make it clear that all of our patients believed they were harmed in one or several of these ways. Indeed, attack and rejection by the est trainer occurs universally in the training process. While expectations (by the leader and the mobilized group of trainees) have been experienced as coercive, they are also contradictory and bewildering. The possibility of input overload is structurally enhanced by the marathon format, aimed at overwhelming defenses by sustained pressure. Finally, the trainee's unrealistic goals are experienced as being simultaneously encouraged and disavowed by the leader.

psychological injury and exposes a virtually unscreened and highly stressed population to it.

Psychodynamics

Speculation about the psychodynamic mechanisms that might explain the major regressions seen in our cases can only be tentative, since our data are not based on long-term controlled study.

The est training is structured to promote regression. Oral intake, urination, and defecation are regulated by the trainers, as are motility and communication. This infantalizes the participants while elevating the leader to a position of omnipotence. Trainees deal with this regressive pull in a variety of ways. Some become observers and distance themselves from the process. Some submit passively. Others may question the process aggressively; the leader's response to their challenge is often delivered in an authoritarian, confrontational, and ridiculing manner that may produce anxiety, humiliation, and fear of future retaliation. Fear of the powerful leader is contagious and is enhanced by the agreed-to proscription against leaving the training room and by a mass psychology of ambivalent submission.

One mechanism of defense that may be used to handle anxiety aroused by forced submission to this powerful leader is identification with the aggressor (8), i.e., attempting to deal with the frightening dominance of the leader by becoming like him or her. However, the defensive identification with the aggressor, invoked to ameliorate the participant's anxiety, may also set up conditions that increase the likelihood of psychiatric disturbances. Shafer, in his definition of identification, says,

> In its fullest, the process of identifying with an object is unconscious, though it may also have prominent and significant preconscious and conscious components; in this process, the subject modifies his motives and behavior patterns, and the self-representations corresponding to them in such a way as to experience being like, the same as, and merged with one or more representations of that object. (9, p. 140)

The experiences of merging with and being the same as an object are fundamentally primary process phenomena, while the experience of being like an object is essentially a secondary process phenomenon. Identifications are composites of both of these.

The conduct of the est training elicits conflicts over dominance and submission that often generate signal anxiety. In response to this signal, an identification with the aggressor is mobilized in addition to other characteristic defenses. Difficulties may occur when a participant whose ego boundaries are defective because of early problems with self-object differentiation identifies with and unconsciously experiences merging with the feared leader. This unconscious experience of merging may precipitate self-object confusion, fear of loss of the self, dissolution of the self, and concomitant instinctual anxiety. In the face of the intensely and unselectively stressful est experience, the identification with the aggressor fails to contain the signal anxiety and paradoxically leads to what may be termed a pathological identification. Psychotic symptoms (alterations in ego functions, delusions, and hallucinations) are then mobilized to prevent the emergence of overwhelming id anxiety (10).

Evidence for a universal (and not necessarily pathogenic) identification with the trainer may be inferred by observation. During the two-weekend course, the trainees' style of dress often begins to mirror the characteristic open-collar style of the leader (2). The est terminology enters the graduate's vocabulary, and graduates often are identifiable outside of the training by virtue of their aggressive, stiffly self-confident, and proselytizing manner.

Examples of a more pathological identification with the aggressor include Mr. B (case 2 in our first paper), who, after taking the trainer's seat on the stage, experienced dissolution of the self, overwhelming anxiety, and subsequent delusions and hallucinations. Ms. D (case 4) felt she was the unacknowledged "other half of Werner Erhard." In case 7, Ms. G's pathological identification was probably associated with fantasies of incorporating the leader.

We have postulated that an overdetermined and pathological reliance on identification with the aggressor is central to the production of psychiatric casualties among est participants. How then would one account for positive outcomes, i.e., those people who report major improvements in emotional well-being and adjustment after est? (We assume that such improvements may occur, even after placebo-effects and other artifacts are considered. A determination of the frequency, extent, and duration of such changes transcends our data.)

We believe the same elements to be at work, but in a more favorable climate. An individual may have contact early in life with a threatening and ambivalently held object, without being as intensely traumatized as we speculate our est casualties were. Their earlier relationships may have been less noxious because the object was not as intrusive or menacing, or the contact may have been moderated by circumstances, e.g., availability of other need-satisfying objects or later or briefer exposure to the ambivalently valued and powerful object. In such a manner, the individual may retain some identification with the powerful object without being as inclined to fuse with him. In the setting of the est experience, a regression may occur that does not threaten ego-integrity but does provide the opportunity for an integration of the old introjects and a mastery of this early trauma.

CONCLUSIONS

Seven cases of psychological complications associated with exposure to est have been presented and

discussed. The nature of our material does not permit generalization with regard to causality and rate of occurrence. However, the group and psychodynamic explanations we have presented may, if substantiated by future systematic research, explain these findings. Specific consideration should be given to the potential significance of the leadership style of est trainers and the defensive maneuvers mobilized in trainees.

Success Rates in Psychiatry and Neurology Certification Examinations

BY MILTON GREENBLATT, M.D., JEAN CAREW, PH.D., AND CHESTER M. PIERCE, M.D.

The authors traced the progress of a sample of 200 psychiatrists and 150 neurologists on the ABPN examination. Overall success rates were high—64% of psychiatrists and 75% of neurologists became Board-certified. Performance on the written exam was a significant predictor of outcome for both groups—88% of psychiatrists and 94% of neurologists who passed Part I on their first try eventually obtained certification. Given the criticism that has been directed toward the oral exam, it was interesting that only 10% of psychiatrists and 5% of neurologists failed to become diplomates because of difficulties with Part II. Future research will deal with the validity and reliability of the oral exam.

IN THE PAST five years the American Board of Psychiatry and Neurology (ABPN) has undertaken research efforts designed to guide policy decisions in its mission of certifying specialists. We hope that this article—the first in a series—will inform relevant constituencies as well as stimulate constructive criticism.

We followed a cohort of applicants in their pursuit of certification. All members of this cohort were licensed physicians who had finished residency training in psychiatry or neurology and had completed at least two years of experience in the field, making them eligible to take Part I, the written portion of the ABPN examinations. Upon successful completion of Part I, these candidates took oral examinations (Part II), during which they interviewed patients and were examined by diplomates of the Board. A candidate could pass, condition one specialty, or fail the oral examination on his/her first attempt, but on second attempts candidates either passed or failed. During the time this cohort was studied, a candidate who failed the oral examination a second time was required to wait two years before trying again. A candidate became a diplomate of the ABPN after he/she passed both Part I and Part II. This study reports on the successes and failures experienced by a sample of candidates over a four-year period in their quest for certification by the Board.

METHOD

The names of 214 psychiatrists and 152 neurologists were randomly selected from applicants who were accepted for the ABPN Part I examination in 1972. Of these applicants, 200 psychiatrists and 150 neurologists actually took the examination; the remainder simply did not show up to take Part I. The success of candidates on the Part I (written) and Part II (oral) examinations was then tracked over a four-year period from 1972 to 1976. The 1972 Part I examination was chosen as the starting point because various changes in the examination rules and content made in previous years had stabilized by that time. The January 1976 oral examination was chosen as the endpoint because it was

Dr. Greenblatt is President, Dr. Carew is Research Consultant, and Dr. Pierce is Secretary, American Board of Psychiatry and Neurology. Dr. Greenblatt is Professor of Psychiatry and Assistant Dean, School of Medicine, University of California, Los Angeles. He is also Chief of Staff, Brentwood Veterans Administration Hospital, Wilshire and Sawtelle Boulevards, Los Angeles, Calif. 90073. The authors wish to acknowledge the assistance of the staff of the American Board of Psychiatry and Neurology, especially Ms. Kathy Engle and Ms. Dona McCall, for compiling the data used in this study.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

TABLE 1
Success on Part I and Subsequent Performance

Candidate Group	Psychiatry (N=200) Number	Psychiatry (N=200) Percent	Neurology (N=150) Number	Neurology (N=150) Percent
Passed Part I on first try	136	68.0	108	72.0
Part II, try 1				
Pass	96	70.6	82	76.0
Condition/fail	38	28.0	24	22.2
Decline	2	1.4	2	1.8
Part II, try 2				
Pass	24	17.6	18	16.6
Fail	14	10.4	6	5.5
Final status				
Diplomate	120	88.2	100	94.4
Not certified	16	11.8	8	5.6
Failed Part I on first try	64	32.0	42	28.0
Part I, try 2				
Pass	14	21.9	14	33.3
Fail	18	28.1	11	26.2
Decline	32	50.0	17	40.4
Part II, try 1				
Pass	5	7.8	8	19.0
Condition/fail	9	14.1	6	14.3
Part II, try 2				
Pass	3	4.7	4	9.5
Fail	6	9.4	2	4.7
Final status				
Diplomate	8	12.5	12	28.5
Not certified	56	87.5	30	71.5

the last examination for which data were available for use in this study.

RESULTS

A total of 64% of the psychiatrists in our sample obtained ABPN certification in the four-year period; 48% passed both exams on their first attempts. Other psychiatrists passed Part I on the second try and were then successful with Part II (2.5%) or passed Part I on the first try but had to take Part II twice (12.5%). A small percentage of candidates in psychiatry (1.5%) had to repeat both the written and the oral exams before becoming diplomates.

Findings for candidates in neurology were similar, although their rates of success were generally higher than those for psychiatrists. Of the 150 neurologists in the sample, 74.7% obtained ABPN certification in the four-year period. Approximately 55% were successful after taking the written and oral exams only once; 5.5% had to repeat the written exam, 12% had to repeat part or all of the oral exam, and 2.7% had to take both exams a second time.

For both psychiatrists and neurologists, initial success or failure on the written exam seemed particularly significant. The data in table 1 indicate that of the 136 psychiatrists who passed Part I on their first try, 88.2% eventually obtained certification, although 17.6% had to repeat Part II. Similarly, of the 108 neurologists who passed the written exam on their first attempt, 94.4% became diplomates in the four-year period. However, of the 64 psychiatrists who failed Part I on their first try, only 8 (12.5%) were ultimately successful, and of the 42 neurologists who failed Part I initially, only 12 (28.5%) were eventually certified.

There are several reasons why candidates who initially failed the written exam did not achieve certification. Many of these candidates simply declined to repeat Part I (50% of psychiatrists and 40.4% of neurologists). Some retook Part I but failed again (28.1% of psychiatrists and 26.2% of neurologists). A few passed Part I on their second attempt (21.9% of psychiatrists and 33.3% of neurologists), but several individuals in this group subsequently failed to pass Part II after two attempts (9.4% of psychiatrists and 4.7% of neurologists).

Thus, although the oral exam has been severely criticized as being too stringent, relatively few candidates (10% of psychiatrists and 5.3% of the neurologists) failed to become diplomates because of difficulties with Part II. For most, the major stumbling block was the written exam: they either failed Part I on their first try and declined to pursue certification further or failed a second time and were compelled by ABPN regulations to wait two years before reapplying.

DISCUSSION

In the past, there has been much discussion by colleagues at meetings and in the literature regarding the pass/fail rates of the ABPN examinations. To our knowledge this study is the first effort to track the fate of a cohort of candidates to determine their actual success rates in the ABPN certification process.

A major implication of the data we have reported seems to be that Part I does serve its essential function as a "screening" device and thus seems to be the major barrier to certification. A candidate who passes the written exam is much more likely to persist in the examination process and become a diplomate of the Board than one who initially fails Part I. It is impressive that 88.2% of psychiatrists and 94.4% of neurologists who passed Part I on their first try were certified within four years, but it is disquieting that only 12.5% of psychiatrists and 28.5% of neurologists who initially failed this exam eventually became diplomates.

No one would deny that candidates who fail an exam are burdened by inconvenience, expense, anxiety, and embarrassment. It is of concern to the Board and to the profession in general that only 48% of psychiatrists and 54.7% of neurologists were able to pass both exams on their first attempts. This may mean that the exams are deficient, that candidates are insufficiently prepared, or that the exams, despite an admitted need for further improvement, do serve to maintain essential professional standards by not permitting overly easy access to specialty status. One may argue that the

ABPN standards implied by these success rates are too stringent—or too lenient. Our findings demonstrate that certification is within the reach of most candidates on the present exams: 64% of psychiatrists and almost 75% of neurologists did become diplomates, a success rate that is comparable to that of other medical specialty branches.

Of specialists who passed Part I without difficulty, eventually 88.2% of psychiatrists and 94.4% of neurologists received their diplomate. Of specialists who failed Part I on their first try but passed subsequently, 12.5% of psychiatrists and 28.5% of neurologists became Board-certified. Of all those who started the exam process 60% of psychiatrists and 66% of neurologists were certified with at most one repeat. Although the Board receives many comments from colleagues who are critical to varying degrees of the exam process, almost all are persuaded that oral examination, especially in psychiatry, is essential. The obvious problem is to ensure that the oral examination is valid and reliable. Future reports will deal with efforts to achieve this goal.

An Examinee's Perspective on Board Certification

BY BEN MAURICE BROWN, M.D.

The author reviews the objectives, sources, preparation, and test-taking strategies commonly used by successful candidates for the certification examination of the American Board of Psychiatry and Neurology, Inc. He suggests that examinees can benefit from the preparation process as well as increase the probability of passing by adopting these strategies.

THE PROCESS of certification in psychiatry by the American Board of Psychiatry and Neurology, Inc. (ABPN), has acquired increasing importance in the past five years for individual psychiatrists and for the institutions with which they are affiliated. During this period the certification process has been subjected to critical scrutiny within the psychiatric profession in the literature (1, 2) and in professional meetings (3). Furthermore, in the past five years the ABPN has promulgated a number of substantial refinements in its certification procedure to improve both the logistics and the reliability of the examination process. These events have focused attention on the status of Board certification as the prevailing standard for professional competence in psychiatry in the United States. In this regard psychiatry is moving toward an alliance with other medical specialties in viewing Board certification as a significant criterion of specialty status. Certification may also come to play a central role in recertification and third-party payment schemes in coming years.

Dr. Brown is Lecturer, Department of Psychiatry, University of Arizona School of Medicine, and Staff Psychiatrist, Mental Health Section, Student Health Service, University of Arizona, Tucson, Ariz. 85721.

The author wishes to thank Dr. Alan Levenson, Chairman, Department of Psychiatry, University of Arizona School of Medicine, for his valuable assistance in critiquing this paper.

CRITICISM AND REFORM

Since 1975 professional criticism of Board examinations in the literature (1) and in professional meetings (3) has tended to focus on several allegations, including ambiguity in defining criteria for passing, logistical complexity, lack of assessment reliability, anxiety-provoking setting, and absence of a spontaneous feedback mechanism for candidates and for training program directors. However, it must be evident that the assessment tools used by the ABPN, whatever their shortcomings, bear far greater similarities to than differences from standard measures for assessing competence as a physician (e.g., the National Board or Flex examinations) and as a specialist in other areas of medicine (e.g., specialty board examinations in orthopedic surgery or dermatology).

Because ABPN examinations have evolved through a selective process like other medical certifying examinations, criticism of the Boards might best be taken as a source of input for refining a tool rather than an excuse for abandoning an encumbrance (2). For example, although efforts to increase the reliability of the oral part of the Boards (Part II) are certainly worth-

while, one could hardly expect to make a valid assessment of clinical competence without observing a candidate's immediate evaluation of clinical data. In any event, Board examinations continue to provide the best standard measure of theoretical mastery and clinical competence developed to date in psychiatry.

In the past three years the ABPN has taken a number of steps to reform the certification process and the assessment tools involved (4). Some of the changes promulgated include elimination of the two-year experience requirement between completion of psychiatric residency and eligibility for Part II, use of videotaped interviews for one hour of clinical psychiatry and one hour of clinical neurology for Part II, selection of multiple sites closer to the candidates' area of residence for Part II, provision for selected feedback by request on examination performance for candidates who condition or fail, provision for feedback to training program directors on the performance of their trainees, and expansion of detailed guidelines for the examiner's evaluation of Part II candidates. Some of these changes would appear to substantially alleviate the logistical difficulties faced by examinees; others aim at improving the reliability of examination procedures.

In view of the increasing importance of Board certification, psychiatrists planning to prepare for the examination would do well to maximize the benefits of the preparation process itself as well as try to increase the probability of successfully completing the examination. From the examinee's standpoint a number of general principles might bear reviewing in this regard. These principles can be categorized under the four general headings of objectives, sources, preparation, and test taking.

OBJECTIVES

At least four major objectives may be defined for the preparation process for Part I and Part II of the Board examination: 1) train to basic competence in all branches of psychiatry and to familiarity with all branches of neurology (Parts I and II), 2) develop an organized core framework for understanding new data from any branch of psychiatry and neurology (Part I), 3) review subspecialties of interest in detail (Part I), and 4) refine clinical diagnostic and treatment planning skills (Part II).

The first of these objectives would promote breadth of understanding for the subspecialist, e.g., the psychopharmacologist training to basic competence in dynamic psychiatry. The second would provide a source of reference for integrating new data from other subspecialties of interest, e.g., the psychoanalyst acquiring a core knowledge of forensic psychiatry, permitting integration of new data on peer review legislation affecting confidentiality. The third objective would permit a thorough review of a subspecialty interest area, e.g., the forensic psychiatrist reviewing in detail state legislation governing expert psychiatric testimony. The fourth would provide the opportunity to hone clinical evaluative skills to a fine edge, e.g., the dynamic psychiatrist refining his or her ability to do a rapid neuropsychiatric diagnostic workup and treatment plan formulation.

SOURCES

The second group of principles for consideration concerns the sources for literature review. Given a limited amount of preparation time, Board candidates must select the resources on which they will primarily rely from a wide variety of excellent literature. Since it is not practical to read in detail all of the available reference material in psychiatry, many successful Board candidates have begun their preparation by selecting one concise but thorough text providing a synopsis of psychiatry and one equivalent text in neurology. Successful candidates often study such texts intensively, reviewing and perhaps outlining each major subject area. They might then consult more detailed reference texts for a thorough review of particularly important areas.

Important areas for review for Part I include detailed factual data on subjects ranging from neuroanatomy to forensics. Basic science areas such as neuroanatomy and neurophysiology often require separate review sources in addition to standard psychiatry and neurology texts. There are several excellent but concise neuroanatomy and neurophysiology review texts. Some candidates also use review question books to survey their detailed factual knowledge in different areas of psychiatry and neurology.

Particularly important areas for the more clinically oriented Part II examination include diagnostic and treatment planning as well as clinical procedures applicable to the major clinical entities in psychiatry and neurology. Thus, clinical chapters in major texts are particularly helpful in clarifying important differential diagnostic distinctions and treatment procedures. An important resource area for both Part I and Part II is the wealth of recent reports of major findings in the journal literature of the past four years. Major theoretical papers and reports of carefully controlled clinical studies involving large numbers of patients provide invaluable source material for Board review.

In summary, there are at least five areas of the literature from which resources may be selected for review in preparation for Boards: psychiatry texts (5–8); neurology texts (9–12); recent journals, such as the *American Journal of Psychiatry, Archives of General Psychiatry, Archives of Neurology,* and *Brain*; neuroanatomy and neurophysiology texts (13–16), and review question books (17, 18). It should be noted that these references are not intended to summarize all the excellent available resources but to provide several examples in each of the five areas of resources that successful Board candidates generally review.

PREPARATION

The third set of principles for consideration concerns preparation. By virtue of their lengthy training and extensive test-taking experience, psychiatrists tend to develop a variety of successful examination preparation strategies that might serve as guidelines for Board preparation. At the same time, a number of general preparation guidelines are commonly cited as helpful by successful Board candidates. These general guidelines aim at providing candidates with adequate preparation inputs, time, practice in clinical skills, and familiarization with examination format.

One frequently recommended guideline involves systematically reviewing all major branches of psychiatry on the basis of literature resources. This review can be enhanced by preparing written outlines for each major topic in psychiatry. Some candidates also find it helpful to attend selected seminars and meetings in psychiatry to complement their reading.

A widely accepted guideline in preparing for Part II involves taking opportunities to personally interview, examine, and discuss patients with psychiatric and neurological disorders. This is especially true for candidates who arrange to repeatedly perform brief history, mental status, and neurological examinations followed by examination by preceptors who use a format similar to that of Part II. Making rounds to see selected psychiatry and neurology patients with a Board-certified specialist is also often cited as helpful.

Another guideline concerns the amount of time required for preparation. Naturally, this factor is highly variable among different candidates. Most successful candidates would probably agree that 4–5 hours a week for the 4–6 months before the examination is ample for review purposes. However, it is common for the preparation time to increase to 10 hours a week in the fortnight before the exam in order to capitalize on short-term retention of details.

A final guideline that might prove helpful is to decide on a clearcut contingency plan in the event of conditioning or failing. Barring major logistical obstacles to retaking the examination, conditioning or failing may provide helpful clues for a subsequent attempt. Conditioning may imply a weakness in one particular area of preparation, while failing may imply broader gaps of knowledge and test-taking skills. A disappointing initial outcome may be turned into an opportunity to identify specific deficiencies in the candidate's initial preparation. Subsequent preparation might then correct such deficiencies by focusing on a thorough review of underprepared topics, an increased effort to practice clinical examination skills, or the development of techniques to allay stress-induced anxiety.

TEST TAKING

The fourth and final category of principles involves the test-taking process. One major aim in this area is to reduce the candidate's anxiety to a level that will not markedly impair his or her recall of important facts or performance of clinical skills. This is vital because many candidates who fail or condition the Board examination appear to show not just a mild but a substantial decrement in performance secondary to excessive anxiety. Competent performance under stress is certainly a necessary aspect of the physician's role and therefore needs to be assessed in the Board certification process. The Board candidate, in turn, needs to minimize adverse stress effects and optimize the probability of responding in a basically sound and adaptive fashion in the face of examination stress. With respect to the test-taking procedures, a number of guidelines may prove useful.

Applying early is likely to facilitate obtaining one's choice of a favorable examination site. Arriving early at the site may permit a relatively leisurely day before the examination as well as allowing ample leeway for dealing with possible complications in transportation and lodging. Reviewing notes and selected text material for up to two hours on the night before the test should probably prove sufficient; 99% of the reviewing should be completed by that time. It may also be helpful to plan to use the examination as a self-measure of theoretical and clinical skills already mastered as well as special areas meriting further study. After all, most candidates who pass as well as those who condition or fail could profitably learn more about certain specialty areas. Last, but not least, it may prove helpful during the examination for candidates to be supportive of patients' roles as volunteers as well as examiners' efforts to be fair but thorough evaluators. Such an attitude might well enhance the potential benefits of the complex and stressful Board examination process for all participants—candidates, patients, and examiners.

CONCLUSIONS

Candidates preparing for the ABPN certification examination undertake a process aimed at affirming their role as medical specialists. This is a role that is becoming increasingly appropriate for psychiatrists. In fact, ABPN examinations have come to assume increasing importance in psychiatry as the specialty has shown educational and clinical developments increasingly parallel to those in other medical specialties.

Contemporary medicine is becoming increasingly concerned with the development and maintenance of professional competence among providers of health care, a concern that has become influential in psychiatry in several areas. In psychiatric training programs, conpetency-based residency education (19, 20) is becoming more prominent. In continuing education, a broad voluntary self-evaluation program has recently been developed (21). In certain clinical service agencies, peer review of clinical treatment procedures has been instituted (22, 23). In specialty certification, ABPN examinations are increasingly assuming the

role of a major index of professional competence in psychiatry. Thus, in summary, the psychiatrist undertaking the process of preparing for and taking Boards encounters a unique opportunity both to train to broad competence in his or her chosen specialty and to receive professional and public accreditation for success in this venture.

From Board Candidate to Rookie Examiner

BY MICHAEL J. NAPOLIELLO, M.D.

The author describes his experience as a candidate for the American Board of Psychiatry and Neurology, Inc., examinations one year and as an oral examiner the next. He discusses the oral examination process, listing the errors most frequently made by candidates.

THE EXPERIENCE of taking the oral examination of the American Board of Psychiatry and Neurology, Inc. (ABPN), has been vividly if not accurately described in the literature (1–3). The predominant tone of these reports is less than positive. In attempting to assess these anecdotes, one has to question the degree of self-selectivity involved. Does the silent majority of candidates who pass the oral examination remain so because the ordeal is over with and they would just as soon forget it, or is the relief of passing a weaker motivator to verbalize than the anger and frustration of failing? In this article I will not attempt a scientific resolution of the matter; rather, I will describe the experience of looking at the oral portion of the Board examination from a unique perspective—as a candidate one year and an examiner the next.

At the orientation session for candidates in St. Louis, Mo., in October 1975, the Executive Secretary of the Board expressed the hope that after certification some of the candidates present would join the ranks of oral examiners. On the basis of a modest degree of previous experience and an interest in oral and written examinations in medical school settings, I decided to accept the invitation.

Dr. Napoliello is Assistant Clinical Professor of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio 45229.

I have described my own experience with the ABPN examination elsewhere (4). This experience had been positive but exacting. On the oral examination, I was treated fairly and courteously by all 6 of my examiners. Both psychiatry hours went smoothly; nearly all of the questions focused on the patient and the physician-patient interaction. My neurology hour, however, produced greater discomfort. The patient had complex and confusing extracranial findings. Despite a reasonable degree of neurological sophistication for a psychiatrist, I felt like a fish out of water. Fortunately, the examiners were understanding; by skillful inquiry they were able to prevent a few awkward moments from becoming a catastrophic half-hour.

The experience was both dissociative and draining. I found myself getting off the hotel elevator on the wrong floor, forgetting names of other candidates I had met a day or two previously, and feeling too fatigued to leave my room. This "pseudodelirium" disappeared by the following day, but the fatigue lasted several more days, along with gnawing anxiety as I waited for the good word from Chicago. I felt almost ashamed to have gotten so "psyched-up," but I found this to be well within the norm for Board candidates.

THE EXAMINATION PROCESS

One year later, I was a rookie examiner on a plane to Chicago, leafing through the same books and notes I had studied as a candidate. A few weeks earlier I had received a detailed orientation in the mail describing the nature and format of the examination, including an explicit caveat against inappropriate behavior toward candidates. This was followed up by a 3-hour orientation session the day before the examination. This session included more detailed instructions on format and a showing of sample videotapes, although my examining team was one of several that were not involved with the videotape portion of the examination.

The team to which I was assigned consisted of 14 examiners (12 men and 2 women), plus an additional psychiatrist who served as section chief. There was 1 other novice examiner in the group; he had become certified 6 months previously. Each candidate in our section was examined by 2 of us, 1 of whom served as primary examiner and the other as "floating" examiner. The primary examiner spent the entire hour with the candidate (30 minutes of patient interview followed by 30 minutes of questioning). The "floater" was expected to cover two candidate examinations within that hour. The section chief also participated as a floater. Immediately before each examining hour, the section chief introduced the candidate to his or her primary examiner. Examiners were expected to disqualify themselves if they happened to have a personal or professional relationship with the candidate.

The candidate was given 30 minutes to interview the patient. The examiner usually informed the candidate when 2–5 minutes remained. A question-and-answer session followed the interview and focused primarily on the clinical presentation of the patient: history, mental status findings, differential diagnosis, treatment, and prognosis. Questions unrelated to the patient interview were less frequently asked. The entire gamut of psychiatry was considered fair game for these questions. Minutiae and trivia were generally avoided, with the intent of highlighting sound clinical skills rather than pedantry. Morgenstern has reviewed the problems of patient interviewing and candidate questioning (5).

Following the examination hour, the primary examiner and the floater met for about 15 minutes to discuss the candidate's performance and to decide on a grade. The primary measures on which the rating was based included the ability to establish rapport with the patient, obtain information in a structured manner, and use the information to make a thoughtful *initial* approach to differential diagnosis and management plus the demonstration of an adequate amount of general psychiatric knowledge.

In my experience, no candidate was treated unceremoniously, nor was there any display of academic bravado on an examiner's part. Every effort was made to allow the candidate to demonstrate his or her fund of psychiatric knowledge in a problem-solving context within the allotted time.

THE CANDIDATES

I examined a total of 16 candidates, either as primary examiner or floater, within the 2-day period. The quality of interviews varied. A few were excellent, a few were poor, and the majority were marginal to satisfactory.

The most common interview errors included the following:

1. Failure to allow the patient to "tell the story." Too often the interview approach was mechanical, as though the candidate were going through a symptom checklist. This tended to impede the pursuit of emotional "leads" presented by the patient.
2. Too abrupt closure of the interview. The candidates often failed to decelerate as the end of the interview approached.
3. Inability of the candidate to control his or her own anxiety level. At times, this caused the patient's anxiety to increase; on one occasion it resulted in a candidate's being insulted by a delusional schizophrenic patient. Another candidate kept looking back and forth several times a minute from the patient to me; this made the patient uncomfortable.
4. Awkwardness and inconsistency of the interview structure, manifested by a great deal of jumping around and resulting in a further increase in candidate anxiety.

The errors most commonly observed during the question-and-answer period included the following:

1. Inability to summarize. This was noticeable in

the majority of the candidates I observed. Unfortunately, psychiatry has become so enamored of dealing with various levels of communication that we sometimes fail to teach our trainees to deal skillfully with the reality level. The ability to distill a mass of information and outline a problem and an initial working solution is essential to any profession. It is a sine qua non of being able to communicate effectively with others. Psychiatrists with experience in liaison psychiatry can well appreciate the value of this approach in their daily efforts to deal with physicians in other specialties.

2. Difficulty in coming to the point. This is an extension of the previous problem. I observed candidates who would digress in the middle of their answer and not succeed in finding their way back to the original question. One candidate mentioned Prolixin while discussing a patient's proposed management. When I asked him to tell me something about Prolixin, he proceeded to discuss Mellaril. The ability to be succinct is a function of self-discipline reinforced by good training.

3. Weakness in differential diagnosis. This was apparent in the majority of candidates. At times the candidate was not able to come up with more than one or two diagnostic possibilities.

4. Use of technical terms without being able to define them. Given the plethora of psychiatric textbooks and glossaries existing today, not to mention *DSM-II* (6), there is no excuse for this.

SYNTHESIS: THE VIEW FROM BOTH SIDES

My experience as a first-time examiner served to confirm the following major impressions made on me as a candidate: candidates are treated courteously and professionally; examiners attempt to elicit the strengths of candidates rather than exploiting their weaknesses; and the content of the examination is fair and relevant. The experience of being an examiner was valuable not only because of the opportunity it afforded to interact with a highly competent group of fellow examiners but also from the standpoint of insight into the oral examination process itself. In spite of the inherent limitations of oral examinations, I was impressed with the objectivity of the entire process and its many checks and balances.

Whether the oral examination in its present form is the most accurate method of evaluating clinical competence is beyond the scope of this article. So too is the problem of how to minimize the candidate's anxiety level to ensure an optimal display of competence. The ability to perform under fire may well reflect the expectations of real-life clinical crises, but the usefulness of the rite of passage mystique is equally debatable. Even if the oral examination were radically modified or eliminated entirely, no examination will be able to fully measure what a psychiatrist is expected to do or guarantee an anxiety-free state to every candidate. On the other hand, in an era when accountability and quality control are accepted professional mandates, it would be tragic, as Lipp suggested (3), to place the burden of proof on the certifying board of a medical specialty that is too often caricatured as unscientific, unstandardized, and undisciplined.

Neurology in the Psychiatry Boards

BY BRUCE D. SNYDER, M.D.

On the basis of his experience as an examiner, the author discusses the problems encountered in assessing psychiatrists' abilities in clinical neurology for certification by the American Board of Psychiatry and Neurology. Hoping to stimulate discussion among trainees, training programs, and the Board, he outlines five paradigms designed to survey neurological knowledge and skill potentially needed by psychiatrists in various situations; these are reduced to specific topics on which Board candidates should be questioned. Relationships between training and examination expectations are discussed.

BOARD examinations for certification in psychiatry and neurology are an attempt to assure some basic uniformity of competence among practitioners. An operational consensus exists among examiners regarding what is to be required of the candidate, but it is not well defined, particularly in evaluations of colleagues in the affiliated specialty. As an examiner, I have had difficulty attempting to fairly assess the psychiatrist's abilities in clinical neurology. This paper presents my approach to this problem; I hope it will stimulate open discussion of the issues raised.

The American Board of Psychiatry and Neurology certifies clinical psychiatrists who practice in a variety of settings with varying patient groups that may be preselected in many different ways. Since an examination cannot be tailored to the predicted practice limitations of each candidate, it must be designed to cover knowledge and skill potentially needed in various situations. In terms of neurology, such situations may be summarized as follows: 1) evaluation of the demented or retarded patient for treatable organic disease; 2) evaluation of the demented or retarded patient who requires behavioral management; 3) evaluation of the delirious or confused patient with or without an altered level of consciousness; 4) assessment of the patient presenting with subjective symptoms that may represent neurologic disease; and 5) possession of sufficient background in neuroscience to interpret pertinent new developments in the psychiatric or neurologic literature.

I am fully aware that these paradigms may not represent actual practice situations for some psychiatrists; but they do represent potential types of referrals a practitioner may have to deal with. Further, psychiatrists functioning in areas where neurologic consultation is unavailable may be asked to help evaluate purely neurologic disease. If the ability to do so is implied by the joint title of the Board, perhaps testing for knowledge up to and beyond these limits is also reasonable. The validity of these paradigms could possibly be established by a survey of psychiatric practices for the frequency of their occurrence. Once established, these data could also provide a baseline for quality-of-care audits prospectively designed to evaluate the Board examination.

I have personally applied these five potential situations to the assessment of psychiatric candidates in the oral examination, and many of the candidates have had a great deal of difficulty with one or more of the areas. Given that the intelligence and motivation of the vast majority of candidates are beyond question, one must conclude that my expectations as an examiner are not congruent with the goals of psychiatric training programs and/or that candidates simply do not expect to be examined in these areas.

The awareness by candidates of the standards for success on the exams can only serve to help them seek and gain further expertise in these particular areas. I think, therefore, that open discussion of the criteria that I use may prompt further comment by others and perhaps aid in stimulating a dialogue among trainees, training programs, and the Board. I should emphasize that my criteria are not in any way officially stated by the Board or its officers and that my views do not reflect any official position of the ABPN.

STANDARDS OF PERFORMANCE

What specifically would I ask of the psychiatric candidate taking the oral examinations? Certainly the recognition of dementia (organic brain syndrome) by mental status examination is well within the area of expertise of the psychiatrist. Knowledge of treatable causes of dementia and the evaluation for these conditions is important, particularly in regard to those few readily treatable, practically emergent situations such as Wernicke's encephalopathy, the precursor to an irreversible amnestic syndrome.

Awareness of the management of the demented or retarded individual should include knowledge of the

Dr. Snyder is Assistant Professor of Neurology, University of Minnesota School of Medicine, St. Paul-Ramsey Hospital, 640 Jackson St., St. Paul, Minn. 55101.

effect of psychotropic medications and their interactions with themselves as well as with other classes of medications. The practitioner should be aware of coexistent and coincidental conditions that could worsen the behavioral performance of such a patient (e.g., sensory deprivation). In view of the fact that the psychiatrist is often called to see the nursing home resident for deteriorating behavior, awareness of such conditions seems like a realistic standard of performance.

Recognition of impairment of consciousness is straightforward if looked for. A psychiatric candidate should be aware that the patient who has taken to bed and is sleeping all day may be either withdrawn on a psychogenic basis or lethargic due to organic disease. The clinician should have a clear idea of the urgency of such a situation and of the need for close monitoring of the patient, in addition to some idea of what must be monitored and when referral is indicated. In this regard, the candidate may be asked about certain basic applicable laboratory studies such as skull X rays, isotope scans, computerized tomography, or the EEG. Knowledge of diagnostic tests need not be asked for in detail but, rather, in terms of which test should be ordered at what point and what it might be expected to reveal.

Psychiatric consultants are not infrequently asked to see confused patients when the differential diagnosis lies between acute or chronic organic brain syndrome (delirium or dementia) and functional disease. This recognition of "organicity," as mentioned above, should be handled well. The psychiatrist should also be able to elicit and recognize such "primitive reflexes" as grasp responses, sucking, and rooting. He should probably be able to recognize asterixis and metabolic tremor as well as choreoathetosis. Awareness of the patient with partial complex seizure disorder (psychomotor seizures, automatisms) is important as these patients can appear to be globally confused or delirious. The candidate should be somewhat aware of the value of the EEG in assessing the confused patient.

The classic problem confronting the psychiatrist and neurologist is the patient with subjective symptoms that may be due to underlying disease of the nervous system. The candidate should be aware of the syndrome of atypical facial pain (these patients almost inevitably receive psychiatric referrals) and of paresthesias and the sometimes bizarre patterns of sensory abnormalities seen with early demyelinating disease. Awareness of the "danger signals" in the presentation of the headache patient is obviously important. The ability to differentiate between organic and functional bases of impotence and a familiarity with the relationship between behavior disorders and seizure activity should reasonably be expected of the psychiatric candidate. The ability to analyze and recognize classic conversion symptoms such as tunnel vision or hysterical blindness, feigned unresponsiveness, or convergence spasm is a reasonable expectation. Of course, one would hope that the candidate would be familiar with neurologic disease that mimics psychiatric disorders: this might include the behavioral abnormalities associated with collagen vascular disease, acute intermittent porphyria, and, for example, Huntington's chorea.

Finally, the candidate should have enough background in neuroscience to interpret new developments in the neurologic literature that may be relevant to the practice of psychiatry: this might include delineation of behavioral patterns related to seizure activity, developments in EEG, etc. It would seem reasonable that the candidate use abstracting services to keep somewhat abreast of neurologic literature.

REALISTIC EXPECTATIONS

It must be pointed out that although I am fairly comfortable with my choice of areas in which to question the candidate, I am unable to precisely define the level of expertise I am seeking. The candidate is asked to conform to my perception of the performance of medical nonneurologists with the provision that the psychiatrist should be quite expert with the mental status examination.

The actual oral examination provides an opportunity to watch the candidate elicit a neurologic history and perform a neurologic examination. Although a good physician can certainly elicit a clinical history, there is no question that one's fund of knowledge of the suspected pathology will guide that history and make it a more effective and efficient tool. Beyond a certain point, is it realistic to ask the psychiatrist to properly steer a history and look for subtler manifestations of neurologic disease? It is not unusual to see a candidate make serious errors of technique or misdirect his attention in the neurologic examination. Assessment is lenient, although candidates may fail on this basis. Learning the technique of examination requires a significant investment of time on the part of the neurology resident before he/she can not only go through the motions but elicit a sensitive, relevant, and reproducible performance.

Psychiatric training programs may provide the psychiatrist with a month of neurology elective; in many cases, there is none whatsoever. With the elimination of the internship, the candidate's total exposure to clinical neurology may be extremely limited. Nevertheless, candidates are asked to perform a neurologic examination and be familiar with such basic tools as the ophthalmoscope, reflex hammer, etc. Whether this is a realistic test criterion is open to question. Whether the psychiatrist should be sufficiently trained to make it a reasonable test criterion could also be a subject for some debate. Should the training program provide a minimum number of hours in supervised clinical neurology, perhaps on an outpatient basis? It may be useful to keep in mind that the availability of neurologic consultation is limited in this country. Psychiatrists

vastly outnumber neurologists and are available in communities of virtually any size. In my own experience, psychiatric colleagues in isolated areas have been asked to see and consult on instances of purely neurologic disease, and certification by a joint Board implied that they knew something about the situation at hand.

I would like to see more discussion about the possible modification of the current test format. Practically speaking, it seems to me that, given his training, it is not currently reasonable to expect the psychiatrist to perform a neurologic examination—but it is reasonable to ask him to possess a fairly broad fund of knowledge concerning the interfaces of psychiatry and neurology. I believe that these areas could be assessed adequately by an expanded written examination that might include test questions modeled after those used by the National Board of Medical Examiners. Specifically, I am referring to sequential questions designed to elicit problem-solving responses in relation to specific clinical situations. This could be done in conjunction with audiovisual aids such as films of patients and, I think, would provide a much more even and objective assessment.

Finally, one must consider certain implications of the examination for the candidate and his training program. Overall figures available from the ABPN suggest a fairly constant Board failure rate for the oral examination of psychiatrists of approximately 40%. This is not broken down in terms of how many failures are due to the neurology examinations. If one accepts that at least a significant number of candidates are failing their neurology examinations (personal observation) and if my view of the examining process and its expected levels of performance are roughly accurate (based on examining with examiners more experienced than I at two sessions of the Boards), then one is tempted to conclude that a significant portion of the psychiatric candidates are not receiving neurologic training congruent with the goals set forth in the examinations. Should the performance of candidates be analyzed according to training programs? Should such information be exchanged between the Board and training programs? Currently, such interchange is limited by legal strictures protecting the privacy of the candidate. Some feedback seems to occur in neurologic circles when performance data from self-assessment examinations are passed back to training program directors

COMMENT

The functions of the ABPN are of significance for psychiatrists, neurologists, and patients. Practitioners may soon rely upon certifying and licensing boards to protect their right to practice in a federally regulated health care system. Board activities involve a good deal of time and expense on the part of a large number of persons. The June 1976 session held in Minneapolis cost $58,000 in fees and $97,000 in expenses ($13,315 for patient and hospital expenses) for the Part II examination alone; 285 psychiatrists and 127 neurologists underwent the process at a cost of $205 per psychiatric candidate and $305 per neurologic candidate. These figures represent a relatively large undertaking for this small community of professionals and a significant and commendable effort at self-regulation. I feel that we owe it to ourselves to make the process as rational, effective, and instructive as possible.

ADDENDUM

Since the acceptance of this manuscript for publication, the American Board of Psychiatry and Neurology has announced (Archives of Neurology, 34:655, 1977) its intention to eliminate the bedside neurological examination for psychiatric candidates in the Part II examination. In addition, the Board has affirmed the desirability of providing feedback regarding candidates' examination performance to training directors if confidentiality can be preserved.

Thyroid Function and Growth Hormone Secretion in Amitriptyline-Treated Depression

BY STEVEN B. LEICHTER, M.D., LARRY KIRSTEIN, M.D., AND NEIL D. MARTIN, M.D.

The authors studied changes in indices of thyroid function prospectively in a group of 11 patients given amitriptyline to treat depression. The drug caused no significant alteration in these indices, but scores on the Hamilton Depression Rating Scale improved significantly. In another group of subjects with depression, the stimulation of growth hormone secretion by L-dopa was unaffected by amitriptyline therapy.

RECENT STUDIES have raised questions about possible interactions between tricyclic antidepressants and endocrine function. It has been suggested that thyroid hormones may alter the action of these agents (1), although their effect on endogenous thyroid function is unclear. Imipramine has been noted to have no effect on chemical indices of thyroid function (2). However, it has been reported to diminish the intestinal absorption of L-dopa (3), which is an accepted stimulant of growth hormone secretion. It is not known whether this would contraindicate the use of L-dopa in evaluating growth hormone secretion in patients who are taking tricyclic antidepressant agents. Since mood disturbance can be a symptom of thyroid disease or pituitary insufficiency, the effects of these drugs on thyroid function and on L-dopa stimulation of growth hormone secretion should be established.

When this work was done, Dr. Leichter was Chief, Endocrine Service, Department of the Air Force, David Grant USAF Medical Center, Travis AFB, Calif. Dr. Kirstein is Assistant Professor, Mt. Sinai School of Medicine, New York, N.Y., and Dr. Martin is Chief, Department of Nuclear Medicine, Kettering Hospital, Kettering, Ohio. Dr. Leichter is now Assistant Professor, Division of Endocrinology, Department of Medicine, University of Kentucky College of Medicine, Lexington, Ky. 40506.

The authors wish to thank Senior Airman Donna M. Russell, Master Sgt. Richard Tinkham, Ms. Pat Daniels, Ms. Macie Neimotka, and Mrs. Viola Martinez for their technical assistance.

We prospectively followed indices of thyroid function in 11 female patients before and after the initiation of amitriptyline therapy. In addition, the effectiveness of L-dopa as a stimulus of growth hormone secretion was studied in depressed patients before and after the inception of amitriptyline therapy and in normal nondepressed subjects.

METHOD

Patients referred to the psychiatry, thyroid, or endocrine clinics of David Grant U.S.A.F. Medical Center were invited to participate in the study. All participants gave informed consent. All patients were seen by a staff endocrinologist (S.B.L. or N.D.M.), and those patients thought to have a depressive illness were evaluated by a staff psychiatrist (L.K.).

A depressive disorder was diagnosed in 11 female patients (23–59 years old), using the criteria of Feighner and associates (4). The initial score on the Hamilton Depression Rating Scale (5) in every patient was 20 or higher. All patients agreed to a trial of therapy with amitriptyline HCl and were seen by the psychiatrist before and 4 weeks after the start of amitriptyline therapy. They were also seen in the thyroid clinic at weekly intervals; physical examinations were performed, patients completed the Zung Self-Rating Depression Scale (SDS) questionnaire (6), and samples of serum were obtained for radioimmunoassay measurement of the serum concentrations of thyroxine (T_4), triiodothyronine (T_3RIA), and thyroid stimulating hormone (TSH), as well as measurement of triiodothyronine resin uptake (T_3U). After the first evaluation by the psychiatrist and endocrinologist, the patients were started on 50–75 mg/day of amitriptyline HCl. At each subsequent visit, the dosage of amitriptyline was adjusted depending on the clinical response and the occurrence of untoward side effects.

A group of 9 depressed subjects (8 women, 26–53

years old, and 1 man, 28 years old) including 3 women from the first group, were given stimulation tests of growth hormone secretion using 500 mg of L-dopa as described previously (7). These patients also fulfilled the Feighner and associates criteria and had Hamilton scale scores above 20. Patients fasted overnight before each test. Samples of serum for measurement of growth hormone concentrations were obtained before and at 30-minute intervals after the administration of oral L-dopa. Each test was carried out for 2 hours after L-dopa administration. Growth hormone secretion in response to the stimulus of L-dopa was judged to be adequate if the serum concentration of growth hormone increased 5 ng/ml or more over the fasting (baseline) value (7). L-Dopa stimulation tests of growth hormone secretion were carried out before and 1 week after the start of therapy with 50–75 mg/day of amitriptyline HCl. Similar tests were also carried out in 4 patients (3 women and 1 man, 24–53 years old) already taking 50–150 mg/day of amitriptyline, who met the criteria applied to the other patients with depression. Each of these 4 patients was taking the medication for periods exceeding 1 week. This test of growth hormone secretion was also given to 8 normal subjects (2 women and 6 men, 25–44 years old) who had no history of depression and were taking no medication.

Assays of serum T_4, T_3RIA, human growth hormone (hGH), and TSH were performed using double-antibody radioimmunoassays from commercially available kits and materials supplied by the National Institute of Arthritis, Metabolism, and Digestive Diseases. Estimation of serum T_3U was also carried out using a commercially available kit.

Statistical analyses were carried out on a Wang 2200B calculator using programs supplied by the manufacturer. Alterations in thyroid function tests were analyzed by using paired t tests, coefficient of correlation, and analysis of variance. Evaluation of growth hormone secretion was analyzed by paired and nonpaired t tests and chi-square analysis.

RESULTS

Of the 11 patients in the thyroid function phase of the study, 10 were still menstruating and 1 was receiving replacement estrogens. No patient was taking oral contraceptives at the time of the study. A subjective decrease in symptoms occurred in 10 of the 11 patients while they were taking amitriptyline HCl. In addition, their SDS scores fell from 71±1.8 to 43±2.9 ($p<.00005$), and their Hamilton scores decreased from 27.7±1.6 to 9.4±1.9 ($p<.0001$).

Physical examination for signs of thyroid dysfunction was unremarkable in all 11 patients before the start of the amitriptyline therapy, and the pretreatment serum levels of T_4, T_3RIA, TSH, T_3U were normal. The institution of therapy with 50–75 mg/day of amitriptyline did not cause a significant or consistent change in these indices of thyroid function in any patient. Similarly, further increases in the daily dose of amitriptyline failed to induce a significant alteration in these thyroid function tests in contrast to the significant decrease in the Hamilton and Zung SDS scores, which occurred in 10 of the 11 subjects.

The effectiveness of L-dopa as a stimulus of growth hormone release was not significantly impaired by amitriptyline. Only 1 patient was taking any other medication, and she was the only menopausal patient. Before amitriptyline therapy, 5 of these 9 patients had an adequate response to L-dopa; 1 additional patient responded adequately to L-dopa after the start of amitriptyline. The sums of the observed growth hormone levels in serum during the tests given before and after amitriptyline therapy were similar (31.8±24.4 and 22.3±12.8 ng/ml, respectively) as were the maximum increments noted in serum growth hormone concentrations over the fasting values (10.6±9.6 and 9.2±6.0 ng/ml, respectively).

Depression alone did not appear to alter the responsiveness of growth hormone secretion to L-dopa. Of the 13 patients and 8 normal subjects who had an L-dopa test before treatment, only 1 was taking medication. An adequate increase in serum concentrations of growth hormone was noted in 8 of the 13 depressed patients (61.5%) and 5 of the 8 normal subjects (71.5%). This difference was nonsignificant when tested by chi-square analysis ($\chi^2=.249$).

The results of L-dopa testing on all drug-free subjects was compared with all amitriptyline-treated subjects. Adequate responses to L-dopa were noted in 11 of 18 drug-free subjects (both control and depressed subjects) and in 5 of 12 amitriptyline-treated patients. The difference was nonsignificant ($\chi^2=.49$). In addition, the sum of observed serum growth hormone levels and the maximum increments over the baseline (fasting) values were similar in both groups.

DISCUSSION

Interactions between tricyclic antidepressant drugs and endogenous endocrine systems have been postulated. A number of groups, particularly Prange and associates, have shown that exogenous thyroid hormone will potentiate the antidepressant effects of imipramine (1) or amitriptyline (8), although this has been disputed recently (9). There is no available evidence to show that untreated patients with depression have any detectable abnormality of thyroid function or that these drugs alter endogenous thyroid function. Prange and associates (1) also reported that imipramine alone failed to alter plasma levels of T_4 or T_3U; they also noted similar increases in plasma T_4 concentrations following the administration of TSH given alone or with imipramine.

Messiha and Morgan (3) have presented data which suggest that imipramine may interfere with intestinal absorption of L-dopa. L-Dopa is an agent frequently used to test the integrity of endogenous growth hor-

mone secretion (7). It has been found to stimulate growth hormone secretion in a high percentage of normal subjects.

This report substantiates the data of Prange and associates (1) that imipramine does not produce clinically significant changes in plasma levels of T_4 and T_3U. In our study, amitriptyline given to euthyroid subjects failed to cause any consistent or significant alteration in plasma concentrations of T_4, T_3RIA, T_3U, or TSH; however, it did produce significant clinical improvement in depression ratings, which suggests that the effect of amitriptyline on depression is not related to detectable changes in endogenous thyroid function.

The efficacy of L-dopa in stimulating hGH secretion was not altered by amitriptyline therapy. No statistical difference was noted in observed hGH concentrations in depressed subjects tested before or after the start of amitriptyline or in the number of subjects who had adequate responses. We noted incidentally that depression did not affect the stimulation of hGH secretion by oral L-dopa, a finding that agrees with previous observations (10, 11).

CONCLUSIONS

This study suggests that thyroid function tests in patients taking amitriptyline are not altered by the drug itself and that these indices of thyroid function are apparently reliable. In addition, L-dopa can still be used as part of an evaluation of hGH secretion in patients on amitriptyline. The statistically nonsignificant changes in hGH secretion noted in those patients taking amitriptyline further underscores an accepted caveat that one should not rely on only one test of the integrity of hGH secretion (12).

Anniversary Reactions Masquerading as Manic-Depressive Illness

BY JESSE O. CAVENAR, JR., M.D., JAMES L. NASH, M.D., AND ALLAN A. MALTBIE, M.D.

The authors suggest that many patients diagnosed as having manic-depressive illness, depressed type, may in fact be experiencing anniversary reactions—time-specific psychological and physiological reactions to a past trauma. They report three cases of cyclic depressive disorder, two of which were first diagnosed as manic-depressive illness, depressed type. Careful, complete interviewing and attention to temporal sequence led to the correct diagnosis of anniversary reaction.

MANIC-DEPRESSIVE illness has been recognized as a clinical entity since the age of Hippocrates. Through the years more attention has been focused on the description and causes of the disorder.
